

# *European Commission*

**Combined Draft (Renewal) Assessment Report prepared according to  
Regulation (EC) N° 1107/2009**

**and**

**Proposal for Harmonised Classification and Labelling (CLH Report)  
according to Regulation (EC) N° 1272/2008**

**DODINE**

**Volume 1**

**December 2023**

**Rapporteur Member State: Spain  
Co-Rapporteur Member State: Germany**

## Version History

| <b>When</b>   | <b>What</b>   |
|---------------|---|
| May 2023      | Initial DRAR – RMS Spain  |
| October 2023  | DRAR revised following receipt of applicant and Co-Rapporteur Member State comments           |
| December 2023 | DRAR revised following EFSA's completeness check<br>DRAR updated after ECHA Accordance check. |

The RMS is the author of the Assessment Report. The Assessment Report is based on the validation by the RMS, and the verification during the EFSA peer-review process, of the information submitted by the Applicant in the dossier, including the Applicant's assessments provided in the summary dossier. As a consequence, data and information including assessments and conclusions, validated and verified by the RMS experts, may be taken from the applicant's (summary) dossier and included as such or adapted/modified by the RMS in the Assessment Report. For reasons of efficiency, the Assessment Report should include the information validated/verified by the RMS, without detailing which elements have been taken or modified from the Applicant's assessment. As the Applicant's summary dossier is published, the experts, interested parties, and the public may compare both documents for getting details on which elements of the Applicant's dossier have been validated/verified and which ones have been modified by the RMS. Nevertheless, the views and conclusions of the RMS should always be clearly and transparently reported; the conclusions from the applicant should be included as an Applicant's statement for every single study reported at study level; and the RMS should justify the final assessment for each endpoint in all cases, indicating in a clear way the Applicant's assessment and the RMS reasons for supporting or not the view of the Applicant.

## Table of contents

|            |  |           |
|------------|--|-----------|
| <b>1</b>   | <b>STATEMENT OF SUBJECT MATTER AND PURPOSE FOR WHICH THIS REPORT HAS BEEN PREPARED AND BACKGROUND INFORMATION ON THE APPLICATION .....</b> | <b>9</b>  |
| <b>1.1</b> | <b>CONTEXT IN WHICH THIS DRAFT ASSESSMENT REPORT WAS PREPARED .....</b>  | <b>9</b>  |
| 1.1.1      | Purpose for which the draft assessment report was prepared .....   | 9         |
| 1.1.2      | Arrangements between rapporteur Member State and co-rapporteur Member State.....   | 9         |
| 1.1.3      | EU Regulatory history for use in Plant Protection Products.....  | 9         |
| 1.1.4      | Evaluations carried out under other regulatory contexts .....  | 9         |
| <b>1.2</b> | <b>APPLICANT INFORMATION.....</b>  | <b>9</b>  |
| 1.2.1      | Name and address of applicant(s) for approval of the active substance .....  | 9         |
| 1.2.2      | Producer or producers of the active substance.....   | 10        |
| 1.2.3      | Information relating to the collective provision of dossiers .....   | 10        |
| <b>1.3</b> | <b>IDENTITY OF THE ACTIVE SUBSTANCE.....</b>   | <b>10</b> |
| 1.3.1      | Common name proposed or ISO-accepted and synonyms .....  | 10        |
| 1.3.2      | Chemical name (IUPAC and CA nomenclature).....   | 10        |
| 1.3.3      | Producer's development code number.....  | 10        |
| 1.3.4      | CAS, EEC and CIPAC numbers.....  | 10        |
| 1.3.5      | Molecular and structural formula, molecular mass.....  | 10        |
| 1.3.6      | Method of manufacture (synthesis pathway) of the active substance.....   | 10        |
| 1.3.7      | Specification of purity of the active substance in g/kg.....   | 10        |
| 1.3.8      | Identity and content of additives (such as stabilisers) and impurities.....  | 11        |
| 1.3.8.1    | Additives.....   | 11        |
|            | CONFIDENTIAL information - data provided separately (DRAR, Vol 4).....   | 11        |
| 1.3.8.2    | Significant impurities.....  | 11        |
|            | CONFIDENTIAL information - data provided separately (DRAR, Vol 4).....   | 11        |
| 1.3.8.3    | Relevant impurities .....  | 11        |
| 1.3.9      | Analytical profile of batches.....   | 11        |
| <b>1.4</b> | <b>INFORMATION ON THE PLANT PROTECTION PRODUCT .....</b>   | <b>11</b> |
| 1.4.1      | Applicant .....  | 11        |
| 1.4.2      | Producer of the plant protection product .....   | 11        |
| 1.4.3      | Trade name or proposed trade name and producer's development code number of the plant protection product.....                              | 11        |
| 1.4.4      | Detailed quantitative and qualitative information on the composition of the plant protection product .....                                 | 11        |
| 1.4.4.1    | Composition of the plant protection product.....   | 11        |
|            | d = 1.0287 g/mL.....   | 11        |
| 1.4.4.2    | Information on the active substances .....   | 11        |
| 1.4.4.3    | Information on safeners, synergists and co-formulants.....   | 11        |
| 1.4.5      | Type and code of the plant protection product .....  | 11        |
| 1.4.6      | Function.....  | 12        |
| 1.4.7      | Field of use envisaged .....   | 12        |
| 1.4.8      | Effects on harmful organisms.....  | 12        |
| <b>1.5</b> | <b>DETAILED USES OF THE PLANT PROTECTION PRODUCT.....</b>  | <b>12</b> |
| 1.5.1      | Details of representative uses .....   | 13        |
| 1.5.2      | Further information on representative uses .....   | 15        |
| 1.5.3      | Details of other uses applied for to support the setting of MRLs for uses beyond the representative uses .....                             | 18        |
| 1.5.4      | Overview on authorisations in EU Member States.....  | 19        |
| <b>2</b>   | <b>SUMMARY OF ACTIVE SUBSTANCE HAZARD AND OF PRODUCT RISK ASSESSMENT .....</b>   | <b>29</b> |

|            |  |           |
|------------|--|-----------|
| <b>2.1</b> | <b>IDENTITY .....</b>  | <b>29</b> |
| 2.1.1      | Summary or identity .....  | 29        |
| <b>2.2</b> | <b>PHYSICAL AND CHEMICAL PROPERTIES [EQUIVALENT TO SECTION 7 OF THE CLH REPORT TEMPLATE]<br/>.....</b>                                       | <b>29</b> |
| 2.2.1      | Summary of physical and chemical properties of the active substance .....  | 29        |
| 2.2.1.1    | Evaluation of physical hazards [equivalent to section 8 of the CLH report template] .....  | 34        |
| 2.2.2      | Summary of physical and chemical properties of the plant protection product.....   | 39        |
| <b>2.3</b> | <b>DATA ON APPLICATION AND EFFICACY .....</b>  | <b>40</b> |
| 2.3.1      | Summary of effectiveness .....   | 40        |
| 2.3.2      | Summary of information on the development of resistance .....  | 40        |
| 2.3.3      | Summary of adverse effects on treated crops .....  | 41        |
| 2.3.4      | Summary of observations on other undesirable or unintended side-effects.....   | 41        |
| <b>2.4</b> | <b>FURTHER INFORMATION.....</b>  | <b>41</b> |
| 2.4.1      | Summary of methods and precautions concerning handling, storage, transport or fire .....   | 41        |
| 2.4.2      | Summary of procedures for destruction or decontamination .....   | 42        |
| 2.4.3      | Summary of emergency measures in case of an accident .....   | 42        |
| <b>2.5</b> | <b>METHODS OF ANALYSIS .....</b>   | <b>42</b> |
| 2.5.1      | Methods used for the generation of pre-authorisation data.....   | 42        |
| 2.5.1.1    | Methods for the analysis of the active substance as manufactured .....   | 42        |
| 2.5.1.2    | Methods for the analysis of the formulation .....  | 43        |
| 2.5.1.3    | Methods for risk assessment .....  | 43        |
| 2.5.2      | Methods for post control and monitoring purposes .....   | 45        |
| 2.5.2.1    | Plants and plant products .....  | 45        |
| 2.5.2.2    | Food of animal origin.....   | 45        |
| 2.5.2.3    | Soil .....   | 46        |
| 2.5.2.4    | Water.....   | 46        |
| 2.5.2.5    | Air .....  | 46        |
| 2.5.2.6    | Body fluids and tissues .....  | 46        |
| <b>2.6</b> | <b>EFFECTS ON HUMAN AND ANIMAL HEALTH.....</b>   | <b>48</b> |
| 2.6.1      | Summary of absorption, distribution, metabolism and excretion in mammals [ <i>equivalent to section 9 of the CLH report template</i> ] ..... | 48        |
| 2.6.1.1    | Short summary and overall relevance of the provided toxicokinetic information on the proposed classification(s).....                         | 51        |
| 2.6.2      | Summary of acute toxicity.....   | 53        |
| 2.6.2.1    | Acute toxicity - oral route [equivalent to section 10.1 of the CLH report template].....   | 53        |
| 2.6.2.2    | Acute toxicity - dermal route [equivalent to section 10.2 of the CLH report template].....   | 55        |
| 2.6.2.3    | Acute toxicity - inhalation route [equivalent to section 10.3 of the CLH report template]....  | 56        |
| 2.6.2.4    | Skin corrosion/irritation [equivalent to section 10.4 of the CLH report template].....   | 58        |
| 2.6.2.5    | Serious eye damage/eye irritation [equivalent to section 10.5 of the CLH report template]..  | 59        |
| 2.6.2.6    | Respiratory sensitisation [equivalent to section 10.6 of the CLH report template].....   | 61        |
| 2.6.2.7    | Skin sensitisation [equivalent to section 10.7 of the CLH report template] .....   | 61        |
| 2.6.2.8    | Phototoxicity .....  | 63        |
| 2.6.2.9    | Aspiration hazard [equivalent to section 10.13 of the CLH report template].....  | 63        |
| 2.6.2.10   | Specific target organ toxicity-single exposure (STOT SE) [equivalent to section 10.11 of the CLH report template] .....                      | 64        |
| 2.6.3      | Summary of repeated dose toxicity (short-term and long-term toxicity) [section 10.12 of the CLH report] .....                                | 67        |
| 2.6.3.1    | Specific target organ toxicity-repeated exposure (STOT RE) [equivalent to section 10.12 of the CLH report template] .....                    | 67        |
| 2.6.4      | Summary of genotoxicity / germ cell mutagenicity [equivalent to section 10.8 of the CLH report template].....                                | 114       |
| 2.6.4.1    | Short summary and overall relevance of the provided information on genotoxicity / germ cell mutagenicity.....                                | 116       |

|            |  |            |
|------------|--|------------|
| 2.6.4.2    | Comparison with the CLP criteria regarding genotoxicity / germ cell mutagenicity .....   | 117        |
| 2.6.4.3    | Conclusion on classification and labelling for genotoxicity / germ cell mutagenicity.....  | 117        |
| 2.6.5      | Summary of long-term toxicity and carcinogenicity [equivalent to section 10.9 of the CLH report template].....                                 | 117        |
| 2.6.5.1    | Short summary and overall relevance of the provided information on long-term toxicity and carcinogenicity .....                                | 128        |
| 2.6.5.2    | Comparison with the CLP criteria regarding carcinogenicity .....   | 131        |
| 2.6.5.3    | Conclusion on classification and labelling for carcinogenicity.....  | 134        |
| 2.6.6      | Summary of reproductive toxicity [equivalent to section 10.10 of the CLH report template] .....  | 134        |
| 2.6.6.1    | Adverse effects on sexual function and fertility – generational studies [equivalent to section 10.10.1 of the CLH report template].....        | 134        |
| 2.6.6.2    | Adverse effects on development [equivalent to section 10.10.4 of the CLH report template] 144  |            |
| 2.6.6.3    | Adverse effects on or via lactation [equivalent to section 10.10.7 of the CLH report template] 159   |            |
| 2.6.6.4    | Conclusion on classification and labelling for reproductive toxicity .....   | 161        |
| 2.6.7      | Summary of neurotoxicity .....   | 161        |
| 2.6.8      | Summary of other toxicological studies .....   | 162        |
| 2.6.8.1    | Toxicity studies of metabolites and impurities.....  | 162        |
| 2.6.8.2    | Supplementary studies on the active substance.....   | 179        |
| 2.6.9      | Summary of medical data and information.....   | 186        |
| 2.6.10     | Toxicological end points for risk assessment (reference values).....   | 186        |
| 2.6.10.1   | Toxicological end point for assessment of risk following long-term dietary exposure – ADI (acceptable daily intake) .....                      | 188        |
| 2.6.10.2   | Toxicological end point for assessment of risk following acute dietary exposure - ARfD (acute reference dose) .....                            | 189        |
| 2.6.10.3   | Toxicological end point for assessment of occupational, bystander and residents risks – AOEL (acceptable operator exposure level).....         | 189        |
| 2.6.10.4   | Toxicological end point for assessment of occupational, bystander and residents risks – AAOEL (acute acceptable operator exposure level) ..... | 189        |
| 2.6.11     | Summary of product exposure and risk assessment .....  | 189        |
| <b>2.7</b> | <b>RESIDUE.....</b>  | <b>190</b> |
| 2.7.1      | Summary of storage stability of residues.....  | 190        |
| 2.7.2      | Summary of metabolism, distribution and expression of residues in plants, poultry, lactating ruminants, pigs and fish.....                     | 191        |
| 2.7.3      | Definition of the residue .....  | 194        |
| 2.7.4      | Summary of residue trials in plants and identification of critical GAP .....   | 195        |
| 2.7.5      | Summary of feeding studies in poultry, ruminants, pigs and fish.....   | 198        |
| 2.7.6      | Summary of effects of processing .....   | 200        |
| 2.7.7      | Summary of residues in rotational crops .....  | 201        |
| 2.7.8      | Summary of other studies .....   | 201        |
| 2.7.9      | Estimation of the potential and actual exposure through diet and other sources .....   | 201        |
| 2.7.10     | Proposed MRLs and compliance with existing MRLs .....  | 207        |
| 2.7.11     | Proposed import tolerances and compliance with existing import tolerances .....  | 207        |
| <b>2.8</b> | <b>FATE AND BEHAVIOUR IN THE ENVIRONMENT .....</b>   | <b>208</b> |
| 2.8.1      | Summary of fate and behaviour in soil .....  | 208        |
| 2.8.1.1    | Route of degradation in soil .....   | 208        |
| 2.8.1.2    | Rate of degradation in soil .....  | 211        |
| 2.8.1.3    | Mobility.....  | 214        |
| 2.8.2      | Summary of fate and behaviour in water and sediment [equivalent to section 11.1 of the CLH report template].....                               | 215        |
| 2.8.2.1    | <i>Rapid degradability of organic substances</i> .....   | 215        |
| 2.8.2.2    | <i>Other convincing scientific evidence</i> .....  | 218        |
|            | <i>Aerobic mineralization</i> .....  | 219        |
| 2.8.3      | Summary of fate and behaviour in air .....   | 222        |
| 2.8.3.1    | <i>Hazardous to the ozone layer</i> .....  | 222        |

|             |  |            |
|-------------|--|------------|
| 2.8.4       | Summary of monitoring data concerning fate and behaviour of the active substance, metabolites, degradation and reaction products ..... | 223        |
| 2.8.5       | Definition of the residues in the environment requiring further assessment.....  | 223        |
| 2.8.6       | Summary of exposure calculations and product assessment .....  | 223        |
| <b>2.9</b>  | <b>EFFECTS ON NON-TARGET SPECIES .....</b>   | <b>224</b> |
| 2.9.1       | Summary of effects on birds and other terrestrial vertebrates .....  | 224        |
| 2.9.1.1     | Summary of effects on birds .....  | 224        |
| 2.9.1.2     | Summary of effects on mammals.....   | 227        |
| 2.9.1.3     | Summary of effects on other terrestrial vertebrates .....  | 239        |
| 2.9.2       | Summary of effects on aquatic organisms [section 11.5 of the CLH report].....  | 240        |
| 2.9.2.1     | Bioaccumulation [equivalent to section 11.4 of the CLH report template].....   | 241        |
| 2.9.2.2     | Acute aquatic hazard [equivalent to section 11.5 of the CLH report template] .....   | 242        |
| 2.9.2.3     | Long-term aquatic hazard [equivalent to section 11.6 of the CLH report template].....  | 247        |
| 2.9.2.4     | Comparison with the CLP criteria.....  | 257        |
| 2.9.2.5     | Conclusion on classification and labelling for environmental hazards .....   | 259        |
| 2.9.3       | Summary of effects on arthropods.....  | 260        |
| 2.9.3.1     | Effects on bees .....  | 260        |
| 2.9.3.2     | Effects on non-target arthropods other than bees.....  | 261        |
| 2.9.4       | Summary of effects on non-target soil meso- and macrofauna .....   | 263        |
| 2.9.4.1     | Effects on earthworms.....   | 263        |
| 2.9.4.2     | Effects on non-target soil meso- and macrofauna (other than earthworms).....   | 264        |
| 2.9.5       | Summary of effects on soil nitrogen transformation .....   | 264        |
| 2.9.6       | Summary of effects on terrestrial non-target higher plants.....  | 265        |
| 2.9.7       | Summary of effects on other terrestrial organisms (flora and fauna) .....  | 267        |
| 2.9.8       | Summary of effects on biological methods for sewage treatment .....  | 267        |
| 2.9.9       | Summary of product exposure and risk assessment .....  | 268        |
| 2.9.9.1     | Summary of risk assessment for bird and other terrestrial vertebrates.....   | 268        |
| 2.9.9.2     | Summary of risk assessment for aquatic organisms.....  | 274        |
| 2.9.9.3     | Summary of risk assessment for bees .....  | 286        |
| 2.9.9.4     | Summary of risk assessment for non-target arthropods .....   | 292        |
| 2.9.9.5     | Summary of risk assessment for non-target soil meso- and macrofauna .....  | 294        |
| 2.9.9.6     | 298  |            |
| <b>2.10</b> | <b>ENDOCRINE DISRUPTING PROPERTIES .....</b>   | <b>299</b> |
| 2.10.1      | ED assessment for humans .....   | 299        |
| 2.10.2      | ED assessment for non-target organisms.....  | 385        |
| 2.10.2.1    | ED assessment for T-modality.....  | 388        |
| 2.10.2.2    | ED assessment for EAS-modality.....  | 395        |
| <b>2.11</b> | <b>PROPOSED HARMONISED CLASSIFICATION AND LABELLING ACCORDING TO THE CLP CRITERIA<br/>[SECTIONS 1-6 OF THE CLH REPORT] .....</b>       | <b>405</b> |
| 2.11.1      | Identity of the substance [section 1 of the CLH report].....   | 405        |
| 2.11.1.1    | Name and other identifiers of the substance .....  | 405        |
| 2.11.1.2    | Composition of the substance .....   | 406        |
| 2.11.2      | Proposed harmonized classification and labelling.....  | 407        |
| 2.11.2.1    | Proposed harmonised classification and labelling according to the CLP criteria.....  | 407        |

# Level 1

**DODINE**

# **1 STATEMENT OF SUBJECT MATTER AND PURPOSE FOR WHICH THIS REPORT HAS BEEN PREPARED AND BACKGROUND INFORMATION ON THE APPLICATION**

## **1.1 CONTEXT IN WHICH THIS DRAFT ASSESSMENT REPORT WAS PREPARED**

### **1.1.1 Purpose for which the draft assessment report was prepared**

According to this Regulation “An application for renewal shall be submitted electronically via a central submission system using the format as set out in Article 7 by a producer of the active substance no later than three years before the expiry of the approval.”

The Company Arysta LifeScience Benelux SPRL notified its intention to support Dodine for Annex I renewal to the Commission, the Rapporteur, the co-Rapporteur and EFSA in order to prepare for the upcoming expiry of Annex I inclusion, in May 2018.

Arysta LifeScience Benelux SPRL applied for the renewal of the active substance Dodine into the list of approved substances according Regulation (EC) No 1107/2009. This draft assessment report was prepared by Spain as Rapporteur Member State for the renewal of the approval of the active substance Dodine according the Regulation (EC) No 1107/2009

### **1.1.2 Arrangements between rapporteur Member State and co-rapporteur Member State**

### **1.1.3 EU Regulatory history for use in Plant Protection Products**

The existing active substance Dodine was included in Annex I of Council Directive 91/414/EEC (Commission Directive 2011/9/EU).

With Commission Implementing Regulation (EU) No 540/2011 implementing Regulation (EC) No 1107/2009 as regards the list of approved active substances, Dodine was included in the list of approved active substances according to Regulation (EC) No 1107/2009.

With Commission Implementing Regulation (EU) No 2020/2007, the expiry date of the approval of Dodine was set to 31.08.2024.

Commission Implementing Regulation (EU) No 2020/1740 sets out the provisions necessary for the implementation of the renewal procedure for active substances, as provided for in Regulation (EC) No 1107/2009 of the European Parliament and of the Council concerning the placing of plant protection products on the market.

### **1.1.4 Evaluations carried out under other regulatory contexts**

No applicable

## **1.2 APPLICANT INFORMATION**

### **1.2.1 Name and address of applicant(s) for approval of the active substance**

Name: Arysta Lifescience Benelux SPRL  
Address: Rue de Renory 26, Boîte 1  
Postal code: 4102  
Ougrée (Seraing)  
Belgium

**Person to contact**

Name and address: [REDACTED]  
 Rue de Renory 26, Boîte 1  
 Postal code: 4102  
 Ougrée (Seraing)  
 Belgium

Phone: [REDACTED]

E-mail: [REDACTED]

**1.2.2 Producer or producers of the active substance**

CONFIDENTIAL information - data provided separately (DRAR, Volume 4)

**1.2.3 Information relating to the collective provision of dossiers**

Not relevant. The Company Arysta LifeScience Benelux SPRL is the only notifier of the active substance Dodine.

**1.3 IDENTITY OF THE ACTIVE SUBSTANCE**

|  |  |

| <b>1.4.6 Function</b>                     | Dodine is a fungicide with protectant and some curative activity.   |
| <b>1.4.7 Field of use envisaged</b>       | <p>Dodine is a fungicide to be used against scab on apples and pears, against cherry leaf spot on cherry and against peach leaf curl on peaches.</p> <p>Dodine is a fungicide with protectant and some curative activity. Dodine is fungitoxic in action preventing disease infection and establishment.</p> <p>Dodine is currently used as a fungicide against scab (<i>Venturia inaequalis/Venturia pyrina</i>) on pome fruits (Apple/Pear/quince/medlar/loquat), leaf spot (<i>Blumeriella jaapii</i>) and leaf scorch (<i>Gnomonia erythrostoma</i>) on cherry, leaf curl (<i>Taphrina deformans</i>) on peach, nectarine, leaf spot of olives (<i>Cycloconium oleaginum</i>), anthracnose of walnut, leaf spot of chestnut and pistachios, leaf blotch of almonds and leaf spot of poplar (<i>Drepanopeziza punctiformis</i>).</p> |
| <b>1.4.8 Effects on harmful organisms</b> | <p>Dodine is fungitoxic in action preventing disease infection and establishment. Dodine is intended to be used as a fungicide against scab (<i>Venturia inaequalis/Venturia pyrina</i>) on pome fruits (Apple/Pear), leaf spot (<i>Blumeriella jaapii</i>) on cherry and leaf curl (<i>Taphrina deformans</i>) on peach, nectarine. Dodine has a translaminar action.</p> <p>Dodine penetrates partially in the leaves and stops the disease. It is a multisite inhibitor acting mainly on the fungus membranes.</p>   |

## 1.5 DETAILED USES OF THE PLANT PROTECTION PRODUCT

**1.5.1 Details of representative uses**

Dodine is currently used as a fungicide on pome fruits (apple/pear/quince/medlar/loquat), on cherry, peach and nectarine, olives, walnut, chestnut and pistachios, almonds, and poplar.

Representative uses for this application are pome fruit, cherry, and peach.

### Compatibility with IPM Strategies

Not relevant

**NECESSARY WAITING PERIODS OF OTHER PRECUATIONS TO AVOID PHYTOTOXICITY EFFECTS ON SUCCEEDING CROPS**

This data point is not applicable; no waiting periods need to be defined.

Succeeding crops are of no relevance for the intended use of Dodine 544 SC.

Limitations on choice of succeeding crops:

Not relevant, Dodine 544 SC is applied in orchards.

**1.5.3 Details of other uses applied for to support the setting of MRLs for uses beyond the representative uses**

#### **1.5.4 Overview on authorisations in EU Member States**

Dodine containing products are widely authorised in European countries. For details, please refer to the following table LIST OF CURRENTLY AUTHORIZED USES AND EXTENT OF USE.

## LIST OF CURRENTLY AUTHORIZED USES AND EXTENT OF USE.

Currently registered uses of Dodine:

| Country  | Product name   | Active substance content | Registration number    | Authorized uses (crops, Harmful organisms, Rates and no of applications, Timing, growth stage) |  |
|----------|----------------|--------------------------|------------------------|--|--|
| Austria  | Syllit 450 SC  | Dodine 450 g/L SC        | 971-0                  | Apple/Pear   | Scab ( <i>Venturia sp.</i> ), 1.5 L/ha in 4 applications (max. 2 after flowering) from the bud opening till 60 days before harvest.  |
|          |                |                          |                        | Cherry   | Leaf spot ( <i>Blumeriella jaapii</i> ), 1.5 L/ha in 2 applications from petal fall till 2 weeks before harvest. Post-harvest applications possible on infected trees.                             |
| Belgium  | Syllit 400 SC  | Dodine 400 g/L SC        | 8418/B                 | Apple/Pear   | Scab ( <i>Venturia sp.</i> ) at 2 applications of 0.68 kg as/ha, from bud opening until 60 days before harvest   |

## 2 SUMMARY OF ACTIVE SUBSTANCE HAZARD AND OF PRODUCT RISK ASSESSMENT

Summary of methodology proposed by the applicant for literature review and for all sections

### 2.1 IDENTITY

#### 2.1.1 Summary or identity

For CONFIDENTIAL information, please refer to DODINE\_DAR\_22\_Volume\_4.

|  |  |
|--|--|
| Chemical name (IUPAC)  | 1-dodecylguanidinium acetate   |
| Chemical name (CA)   | dodecylguanidine monoacetate   |
| CIPAC No   | 101  |
| CAS No   | 2439-10-3  |
| EC No (EINECS or ELINCS)   | 219-459-5  |
| Identity of relevant impurities (of toxicological, environmental and/or other significance) in the active substance as manufactured (g/kg) | No relevant impurities   |
| Molecular formula  | C <sub>15</sub> H <sub>33</sub> N <sub>3</sub> O <sub>2</sub>                        |
| Molecular mass   | 287.4 g/mol  |
| Structural formula   |  |

According to the SANCO/12248/2010 and EFSA Journal 2010; 8(6):1631, the minimum purity for Dodine shall comply with the FAO specification (101/TC/S (1988) (AGP: CP/236)): Dodine: min. 950 g/kg, Water: max. 10 g/kg.

The minimum purity of the technical active substance Dodine is in agreement with the FAO specification.

The representative formulation with trade name Dodine 544 SC is designated as a Suspension Concentrate [Code: SC] and contains 52.88% w/w (544 g/L) of technical dodine.

### 2.2 PHYSICAL AND CHEMICAL PROPERTIES [EQUIVALENT TO SECTION 7 OF THE CLH REPORT TEMPLATE]

#### 2.2.1 Summary of physical and chemical properties of the active substance

Table 1: Summary of physicochemical properties of the active substance

| Property                                    | Value   | Reference  | Comment (e.g. measured or estimated)  |
|---|---|--|---|

### 2.2.1.1 Evaluation of physical hazards [equivalent to section 8 of the CLH report template]

#### 2.2.1.1.1 Explosives [equivalent to section 8.1 of the CLH report template]

Table 2: Summary table of studies on explosive properties

| Method                          | Results   | Remarks   | Reference                   |
|---------------------------------|---|---|-----------------------------|
| Method EC A.14 (983 g/kg TGAS ) | Shock test: not shock sensitivity to explosion.<br>Friction test: not sensitive to friction using a friction load of 360 N.<br>Thermal sensitivity - Koenen test: has been determined not to have thermal sensibility to explosion. | Method EC A.14 is not a standar technique for assessing explosive properties according to CLP criteria. | ██████████ 1998<br>R-98-131 |

2.2.1.1.1.1 Short summary and overall relevance of the provided information on explosive properties

Shock test: not shock sensitivity to explosion.

Friction test: not sensitive to friction using a friction load of 360 N

Thermal sensitivity - Koenen test: has been determined not to have thermal sensibility to explosion.

2.2.1.1.1.2 Comparison with the CLP criteria

No explosivity classification is required. According to point 2.1.4.3 of Annex I of CLP Regulation the acceptance procedure for the hazard class ‘explosives’ does not apply for dodine taking into account that the molecule does not contain chemical groups associated with explosivity considering the examples given in Table A6.1 of Appendix 6 of the UN RTDF Manual of Tests and Criteria.

2.2.1.1.1.3 Conclusion on classification and labelling for explosive properties

No classification proposed based on data conclusive but not sufficient for classification.

#### 2.2.1.1.2 Flammable gases (including chemically unstable gases) [equivalent to section 8.2 of the CLH report template]

Table 3: Summary table of studies on flammable gases (including chemically unstable gases)

| Method                   | Results | Remarks | Reference |
|--------------------------|---------|---------|-----------|
| Not relevant for a solid |         |         |           |

2.2.1.1.2.1 Short summary and overall relevance of the provided information on flammable gases (including chemically unstable gases)

Not relevant for a solid

2.2.1.1.2.2 Comparison with the CLP criteria

Not relevant for a solid

2.2.1.1.2.3 Conclusion on classification and labelling for flammable gases

Not relevant for a solid

#### 2.2.1.1.3 Oxidising gases [equivalent to section 8.3 of the CLH report template]

Table 4: Summary table of studies on oxidising gases

| Method                   | Results | Remarks | Reference |
|--------------------------|---------|---------|-----------|
| Not relevant for a solid |         |         |           |

2.2.1.1.3.1 Short summary and overall relevance of the provided information on oxidising gases

Not relevant for a solid

2.2.1.1.3.2 Comparison with the CLP criteria

Not relevant for a solid

2.2.1.1.3.3 Conclusion on classification and labelling for oxidising gases

Not relevant for a solid

**2.2.1.1.4 Gases under pressure [equivalent to section 8.4 of the CLH report template]**

Table 5: Summary table of studies on gases under pressure

| Method                   | Results | Remarks | Reference |
|--------------------------|---------|---------|-----------|
| Not relevant for a solid |         |         |           |

2.2.1.1.4.1 Short summary and overall relevance of the provided information on gases under pressure

Not relevant for a solid

2.2.1.1.4.2 Comparison with the CLP criteria

Not relevant for a solid

2.2.1.1.4.3 Conclusion on classification and labelling for gases under pressure

Not relevant for a solid

**2.2.1.1.5 Flammable liquids [equivalent to section 8.5 of the CLH report template]**

Table 6: Summary table of studies on flammable liquids

| Method                   | Results | Remarks | Reference |
|--------------------------|---------|---------|-----------|
| Not relevant for a solid |         |         |           |

2.2.1.1.5.1 Short summary and overall relevance of the provided information on flammable liquids

Not relevant for a solid

2.2.1.1.5.2 Comparison with the CLP criteria

Not relevant for a solid

2.2.1.1.5.3 Conclusion on classification and labelling for flammable liquids

Not relevant for a solid

**2.2.1.1.6 Flammable solids [equivalent to section 8.6 of the CLH report template]**

Table 7: Summary table of studies on flammable solids

| Method  | Results                                    | Remarks | Reference                   |
|---------|--|---------|-----------------------------|
| EC A.10 | Technical Dodine is not “highly flammable” |         | ██████████ 2001<br>R-327083 |

2.2.1.1.6.1 Short summary and overall relevance of the provided information on flammable solids

The test material did not ignite and did not propagate combustion. It is not highly flammable by ignition according to the test method EC A.10.

2.2.1.1.6.2 Comparison with the CLP criteria

According to RAC/62/2022/04 document *Assessing physical hazards as part of CLP* if the result of the A.10 test method is “not highly flammable”, no more testing is necessary following REACH Guidance on Information Requirements Chapter R.7a: Endpoint specific R.7.1.10.3.

2.2.1.1.6.3 Conclusion on classification and labelling for flammable solids

No classification proposed based on data conclusive but not sufficient for classification.

#### 2.2.1.1.7 Self-reactive substances [equivalent to section 8.7 of the CLH report template]

Table 8: Summary table of studies on self-reactivity

| Method  | Results                      | Remarks | Reference  |
|---|------------------------------|---------|--|
| EEC Method A16<br>(Relative self-ignition temperature for solids) | No self-ignition temperature |         | ██████████ ██████████<br>██████████ 1998<br>R-98-131 |

2.2.1.1.7.1 Short summary and overall relevance of the provided information on self-reactive substances

No classification proposed based on the results of the test method A.16.

2.2.1.1.7.2 Comparison with the CLP criteria

No classification for self-reactivity is required. According to CLP point 2.8.4.2 of Annex I of CLP Criteria, the hazard class does not apply if there are no chemical groups in the molecule associated with explosive or self reactive properties. Dodine molecule does not contain chemical groups associated with explosive or self-reactive considering the examples given in Table A6.1 and Table A6.3 of Appendix 6 of the UN RTDF Manual of Tests and Criteria.

2.2.1.1.7.3 Conclusion on classification and labelling for self-reactive substances

No classification proposed based on data conclusive but not sufficient for classification.

#### 2.2.1.1.8 Pyrophoric liquids [equivalent to section 8.8 of the CLH report template]

Table 9: Summary table of studies on pyrophoric liquids

| Method                   | Results | Remarks | Reference |
|--------------------------|---------|---------|-----------|
| Not relevant for a solid |         |         |           |

2.2.1.1.8.1 Short summary and overall relevance of the provided information on pyrophoric liquids

Not relevant for a solid

2.2.1.1.8.2 Comparison with the CLP criteria

Not relevant for a solid

## 2.2.1.1.8.3 Conclusion on classification and labelling for pyrophoric liquids

Not relevant for a solid

## 2.2.1.1.9 Pyrophoric solids [equivalent to section 8.9 of the CLH report template]

Table 10: Summary table of studies on pyrophoric solids

| Method  | Results | Remarks | Reference |
|---------|---------|---------|-----------|
| No data |         |         |           |

## 2.2.1.1.9.1 Short summary and overall relevance of the provided information on pyrophoric solids

Dodine is unlikely to be pyrophoric and the test for pyrophoricity according to UN Test N.3 described in Part III, Section 33 of the UN Recommendations on the Transport of Dangerous Goods, Manual of Tests and Criteria should not be performed.

## 2.2.1.1.9.2 Comparison with the CLP criteria

Experience in manufacture and handling shows that the substance dodine does not ignite spontaneously on coming into contact with air at normal temperature.

## 2.2.1.1.9.3 Conclusion on classification and labelling for pyrophoric solids

Dodine is not a pyrophoric solid.

## 2.2.1.1.10 Self-heating substances [equivalent to section 8.10 of the CLH report template]

Table 11: Summary table of studies on self-heating substances

| Method  | Results                      | Remarks   | Reference                |
|---------|------------------------------|---|--------------------------|
| EC A.16 | No self-ignition temperature | Dodine Technical Grade (Batch 6012) Purity 983 g/kg | ██████████ 1998 R-98-131 |

## 2.2.1.1.10.1 Short summary and overall relevance of the provided information on self-heating substances

No self ignition temperature was determined for dodine according to the results of the test method A.16.

## 2.2.1.1.10.2 Comparison with the CLP criteria

Dodine is not classified as a self-heating substance according to the test method A.16. Although the recommended method in CLP Regulation is the UN Test. N.4 described in Part III, Section 33 of the UN Recommendations of the Transport of Dangerous Goods, Manual of Tests and Criteria, according to RAC/62/2022/04 document *Assessing physical hazards as part of CLP* the test method A.16 can be considered conclusive when the result is negative.

Besides, according to the ECHA Guidance on the Application of the CLP Criteria (Version 5.0 – July 2017): *substances or mixtures with a low melting point (< 160 °C) should not be considered for classification in this hazard class since the melting process is endothermic and the substance-air surface is drastically reduced. However, this criterion is only applicable if the substance or mixture is completely molten up to this temperature.* The melting point of dodine is 133.2°C at 101.3 kPa and consequently this hazard class does not apply according to CLP criteria.

## 2.2.1.1.10.3 Conclusion on classification and labelling for self-heating substances

No classification proposed based on data conclusive but not sufficient for classification.

**2.2.1.1.11 Substances which in contact with water emit flammable gases [equivalent to section 8.11 of the CLH report template]**

Table 12: Summary table of studies on substances which in contact with water emit flammable gases

| Method  | Results | Remarks | Reference |
|---------|---------|---------|-----------|
| No data |         |         |           |

2.2.1.1.11.1 Short summary and overall relevance of the provided information on substances which in contact with water emit flammable gases

No data available.

2.2.1.1.11.2 Comparison with the CLP criteria

According to CLP Regulation 2.12.4.1, no classification is required if:

- a) There are no metals or metalloids in the chemical structure, OR
- b) Experience in production or handling shows that the substance does not react with water, e.g. the substance is manufactured with water or washed with water, OR
- c) The substance is known to be soluble in water and form stable mixture.

Since dodine does not contain in its chemical structure metals or metalloids, no classification is required.

2.2.1.1.11.3 Conclusion on classification and labelling for substances which in contact with water emit flammable gases

No classification proposed based on data conclusive but not sufficient for classification.

**2.2.1.1.12 Oxidising liquids [equivalent to section 8.12 of the CLH report template]**

Table 13: Summary table of studies on oxidising liquids

| Method                   | Results | Remarks | Reference |
|--------------------------|---------|---------|-----------|
| Not relevant for a solid |         |         |           |

2.2.1.1.12.1 Short summary and overall relevance of the provided information on oxidising liquids

Not relevant for a solid.

2.2.1.1.12.2 Comparison with the CLP criteria

Not relevant for a solid.

2.2.1.1.12.3 Conclusion on classification and labelling for oxidising liquids

Not relevant for a solid.

**2.2.1.1.13 Oxidising solids [equivalent to section 8.13 of the CLH report template]**

Table 14: Summary table of studies on oxidising solids

| Method         | Results                 | Remarks | Reference                        |
|----------------|-------------------------|---------|----------------------------------|
| EEC Method A17 | No oxidising properties |         | ██████████, 2000<br>R-00-330-SEC |

2.2.1.1.13.1 Short summary and overall relevance of the provided information on oxidising solids

Dodine has not oxidising properties according to the results of the test method A.17.

## 2.2.1.1.13.2 Comparison with the CLP criteria

According to criteria included for organic substances in point 2.14.4.1 of Annex I of CLP Regulation, dodine is not an oxidising solid since it does not contain chlorine or fluorine and it contains oxygen but chemically bounded to carbon and hydrogen.

## 2.2.1.1.13.3 Conclusion on classification and labelling for oxidising solids

No classification proposed based on data conclusive but not sufficient for classification.

**2.2.1.1.14 Organic peroxides [equivalent to section 8.14 of the CLH report template]**

Table 15: Summary table of studies on organic peroxides

| Method  | Results | Remarks | Reference |
|---------|---------|---------|-----------|
| No data |         |         |           |

## 2.2.1.1.14.1 Short summary and overall relevance of the provided information on organic peroxides

No data available. However, since the peroxide group (O-O) is absent in the chemical structure of dodine, the hazard class is not applicable.

## 2.2.1.1.14.2 Comparison with the CLP criteria

Dodine has not contain the peroxide group (O-O) and according to CLP criteria classification is not required.

## 2.2.1.1.14.3 Conclusion on classification and labelling for organic peroxides

No classification proposed based on data conclusive but not sufficient for classification.

**2.2.1.1.15 Corrosive to metals [equivalent to section 8.15 of the CLH report template]**

Table 16: Summary table of studies on the hazard class corrosive to metals

| Method               | Results | Remarks | Reference |
|----------------------|---------|---------|-----------|
| No studies available |         |         |           |

## 2.2.1.1.15.1 Short summary and overall relevance of the provided information on the hazard class corrosive to metals

No data provided.

## 2.2.1.1.15.2 Comparison with the CLP criteria

According to the ECHA Guidance on the Application of the CLP Criteria (Version 5.0 – July 2017) only solids with a melting point below 55°C need to be tested for this hazard class (2.16.4.1) and no classification can be proposed. Since the melting point of dodine is 133.2°C at 101.3 kPa classification is not required.

## 2.2.1.1.15.3 Conclusion on classification and labelling for corrosive to metals

No classification proposed based on data conclusive but not sufficient for classification.

**2.2.2 Summary of physical and chemical properties of the plant protection product**

The appearance of the product is that of an opaque white liquid with a small clear liquid layer on the top and a small sediment on the bottom (claying) homogeneous after gentle shaking, and with a faint chemical odour. It is not explosive, and has no oxidising properties. It has a self-ignition temperature of 404°C. The stability data indicate that after 14 days at 54°C, no decrease of Dodine content is seen (0.0%). It is noted that the product is

more viscous after accelerated storage. Its technical characteristics are acceptable for such a liquid formulation (SC). There is no effect of low temperature on the stability of the formulation since after 7 days at 0°C, neither the appearance nor the technical properties had changed. Dodine 544 SC in its commercial packaging has a shelf-life of at least 2 years and it was also demonstrated stability for 3 years.

## 2.3 DATA ON APPLICATION AND EFFICACY

### 2.3.1 Summary of effectiveness

Dodine is currently used as a fungicide against scab (*Venturia inaequalis/Venturia pyrina*) on pome fruits (apple/pear/quince/medlar/loquat), leaf spot (*Blumeriella jaapii*) and leaf scorch (*Gnomonia erythrostoma*) on cherry, leaf curl (*Taphrina deformans*) on peach and nectarine, leaf spot of olives (*Cycloconium oleaginum*), anthracnose of walnut, leaf spot of chestnut and pistachios, leaf blotch of almonds and leaf spot of poplar (*Drepanopeziza punctiformis*). Representative uses are scab (*Venturia inaequalis/Venturia pyrina*) in apple/pear, leaf spot (*Blumeriella jaapii*) in cherry and leaf curl (*Taphrina deformans*) on peach. Dodine is currently used as a fungicide on pome fruits (apple/pear/quince/medlar/loquat), on cherry, peach and nectarine, olives, walnut, chestnut and pistachios, almonds and poplar. Representative uses for this application are pome fruit, cherry and peach.

Dodine based formulations for foliar spray applications are already authorized for many years in member states of the European Union. No new data is submitted within the framework of this application for the renewal of the approval of the active substance Dodine.

**RMS agrees** with the data and information submitted by the applicant regarding the Guidance SANCO/2012/11251 Guidance Document on the renewal of approval of active substances to be assessed in compliance with Regulation (EU) No 844/2012 (The Renewal Regulation):

*“The dossier should include an overview of the efficacy information concerning representative and supported uses already authorised in Member States according to the format provided in MCA section 3 (see GD SANCO/10181/2013). Information as regards the representative uses and the supported uses has to be reported as part of chapter C 3.3 (MCP section 3). Information about their current authorisation status is reported in Doc D-2. Considering that the substance is approved and authorisations of plant protection products containing the substance have already been evaluated according to the Uniform Principles (Regulation (EC) No 546/2011), no other efficacy documentation is deemed to be necessary at this stage”.*

However, **RMS considers** useful to add summary tables with results of efficacy trials developed during the last years by the notifier, mainly for the representative uses proposed in this submission for the renewal of the active substance. The purpose is to show clearly the efficacy of the active substance. In the Table 1, summary data provided by the notified have been added.

### 2.3.2 Summary of information on the development of resistance

According to FRAC, (group-u12-(guanidines) ---dodine-recommendations-22th-of-december-2020)<sup>1</sup> for recent years no cases of resistance towards Dodine have been found. Nevertheless, resistance cases are known for *Venturia inaequalis* (apple scab) from Canada and the North-Eastern part of the USA. These were reported in the 1970s and 1980s. Some cases of resistance have also been identified from resistance-monitoring programs in Poland and New Zealand. However, these cases are attributed to very intensive, often exclusive use of Dodine (mainly in the USA and Canada) or to the use of Dodine as rescue applications to burn out established scab lesions (Poland). Since that period, the use of Dodine against apple scab has dropped drastically in the USA and Canada. FRAC reports that in New Zealand, sensitivity towards guanidines has not increased since the 1990s and may have actually decreased.

Furthermore, FRAC does not report information on resistance to Dodine for any other diseases or crops even not on pear scab (*Venturia pyrina*).

---

<sup>1</sup> document available at <https://www.frac.info/frac-teams/other-fungicide-recommendations> accessed 6<sup>th</sup> May 2021

FRAC evaluates the general risk for development of resistance against Dodine as low to medium.

### 2.3.3 Summary of adverse effects on treated crops

The crop safety of the representative uses has already been evaluated under Uniform Principles for national registration and found acceptable. Therefore, no specific data on phytotoxicity is required.

### 2.3.4 Summary of observations on other undesirable or unintended side-effects

The representative uses have already been evaluated under Uniform Principles for national registration and found acceptable. Therefore, no information regarding observations on other undesirable or unintended side effects is required.

## 2.4 FURTHER INFORMATION

### 2.4.1 Summary of methods and precautions concerning handling, storage, transport or fire

#### Precautions for safe handling

Appropriate engineering controls: Ensure good ventilation of the workstation.

Hand protection: protective gloves

Eye protection: Safety glasses

Skin and body protection: Wear suitable protective clothing

Respiratory protection: In case of inadequate ventilation, wear respiratory protection.

Do not breathe dust/fume/gas/mist/vapours/spray.

Avoid contact with skin and eyes. Wear personal protective equipment.

#### Storage conditions

Store locked up. Store in a well-ventilated place. Keep container tightly closed.

Store at room temperature

Maximum storage period: 2 year(s)

#### Transport (ADR, IMDG, IATA)

Transport of dangerous goods by land: with regard to ADR 2015 and RID 2015

Hazard Class 6.1

UN Number: 2588

Packing Group: II

Shipping Name: PESTICIDE, SOLID, TOXIC, N.O.S. (Dodine)

#### Firefighting measures

##### Extinguishing media:

Suitable extinguishing media: Water spray. Dry powder. Foam.

##### Specific hazards:

Explosion hazard: Dust may form explosive mixture in air. Hazardous decomposition products in case of fire: Toxic fumes may be released

Protection during firefighting: Do not attempt to take action without suitable protective equipment.

Self-contained breathing apparatus.

Complete protective clothing.

## 2.4.2 Summary of procedures for destruction or decontamination

For containment: Collect spillage.

Methods for cleaning up: Mechanically recover the product.

Other information: Dispose of materials or solid residues at an authorized site.

## 2.4.3 Summary of emergency measures in case of an accident

### Description of first aid measures

First-aid measures general: Call a physician immediately.

First-aid measures after inhalation: Remove person to fresh air and keep comfortable for breathing. Call a physician immediately. Call a doctor.

First-aid measures after skin contact: Wash skin with plenty of water. Take off contaminated clothing. If skin irritation occurs: Get medical advice/attention.

First-aid measures after eye contact: Rinse cautiously with water for several minutes. Remove contact lenses, if present and easy to do. Continue rinsing. Call a physician immediately.

First-aid measures after ingestion: Rinse mouth. Call a poison center or a doctor if you feel unwell. Treat symptomatically.

### Personal precautions and protective equipment

For non-emergency personnel: Do not breathe dust/fume/gas/mist/vapours/spray. Only qualified personnel equipped with suitable protective equipment may intervene.

For emergency responders: Do not attempt to take action without suitable protective equipment (safety glasses, suitable protective clothing, and protective gloves).

### Environmental precautions

For containment: Collect spillage.

## 2.5 METHODS OF ANALYSIS

### 2.5.1 Methods used for the generation of pre-authorisation data

#### 2.5.1.1 *Methods for the analysis of the active substance as manufactured*

Determination of the active ingredient Dodine in the TGAS: The active substance content is determined after dilution in water and methanol / water 9/1 v/v by HPLC/UV. But the specificity of the HPLC-UV method was not demonstrated and a confirmatory method is required.

| Analyte | Method  | Specificity  | Linearity   | Accuracy (Recovery) | Repeatability (Precision)   | Reference       |
|---------|---------|--|---|---------------------|---|-----------------|
| Dodine  | HPLC-UV | no interferences were detected in blank chromatograms, confirmation with FT-IR spectra | 50 to 120 mg/L (6 levels, equivalent to 500 to 1200 g/kg)<br>$r^2 > 0.99$ | Not required        | <u>The relative standard deviation (RSD) was found to be 0.18% (at 983 g/kg).</u> | ██████ R (2016) |

The active substance as manufactured does not contain relevant impurities. Therefore analytical methods for the determination of impurities are not required.

For determination of significant impurities LC-MS/MS and GC-MS/MS methods are used. More information in the confidential Vol 4 of the DRAR.

### 2.5.1.2 *Methods for the analysis of the formulation*

Determination of the active ingredient Dodine in the formulation Dodine 544 SC: The active substance content is determined after dispersion in water and methanol and dilution in a mixture acetonitrile - water containing heptane sulfonic acid. The separation is achieved using HPLC-ion-pair chromatography with ultra-violet detection.

| Analyte | Method                       | Specificity  | Linearity  | Accuracy (Recovery)  | Repeatability (Precision)   | Reference   |
|---------|------------------------------|--|--|--|---|---|
| Dodine  | HPLC-ion-pair chromatography | Since no interferences were detected in blank chromatograms, the specificity requirements were met and the analytical method was found to be specific for Dodine | the range 49-203 µg dodine/mL ( $\pm 50\%$ of the nominal concentration)<br>$r = 1.000$<br>$r^2 = 1.000$ | The mean recovery for Dodine in Dodine 544 SC was determined to be 100.4%. | <u>The relative standard deviation (RSD) was found to be 0.35%.</u> | <br>(2011) |

Adequate analytical methods are available for the determination of Dodine in the representative formulation.

Methods for determination of relevant impurities, co-formulants or components of co-formulants in the plant protection product are not required.

### 2.5.1.3 *Methods for risk assessment*

GC/MS/MS methods after derivatization of dodine and HPLC/MS/MS methods were used for the determination of dodine in support of e-fate, toxicological, ecotoxicological and residues studies.

#### 2.5.1.3.1 **Environmental fate**

##### **Dodine in soil**

Extraction with methanolic solutions, Derivatization with hexafluoroacetyl acetone (HFAA), analysis GC-MSD

LOQ : 10 ppb (ng/g)

Validated working range : 20 – 150 ng/mL.

#### 2.5.1.3.2 **Toxicology**

In brief the methods are as follow:

##### **Dodine in animal diet**

- Extraction with MeOH, derivatization with hexafluoroacetyl acetone (HFAA), analysis by HPLC/UV or by HPLC/FL.

- Derivatization with trifluoroacetic anhydride (TfAA), analysis by GC/FID. Validated in Corning Hazleton Study No. 6157-186 (old study, no longer available)

##### **For operator exposure studies**

Determination of Dodine on glass fiber air sampling filters, T-shirts/long underpants/head bands, socks, gloves and coveralls: Extraction with 1% HCl in methanol/water 50/50 v/v% and analysis by HPLC-MS/MS using ESI+.

LOQ : approximately 5 µg/L

Working range : 2 to 100 µg/L (in 0.1 acetic acid in methanol/water 50/50 v/v%),  $r^2 > 0.99$

### 2.5.1.3.3 Residues

#### Dodine in Dislodgeable Foliar Residues

Dilution with MeOH, analysis by LC-MS/MS

LOQ: 0.5 µg/L

Validated working range: 0.075 ng/mL to 10 ng/mL equivalent to 0.15 µg/L to 20 µg/L in wash solutions

#### Dodine in plant matrices

Method MEREDODINE based on CHIMAC-AGRIPHAR method RPA/DOD/97112 (██████████ 1998): Extraction with MeOH, derivatization with hexafluoroacetyl acetone (HFAA), analysis by GC-MS (quantitation ion 244, qualifiers ions 245 and 399.20), calibration with matrix matched solution, fortified with dodine standard and derivatised prior to analysis.

LOQ in apple: 0.005 mg/kg

Validated working range: 0.0025 µg/mL to 0.5 µg/mL expressed as dodine (equivalent to 0.005 to 1 mg/Kg in apple).

Rhône Poulenc Method 45137, 1996:

Extraction with MeOH, derivatization with hexafluoroacetyl acetone (HFAA), analysis by GC-MS (quantitation ion 243.95, qualifiers ions 244.95 and 399.20), and calibration with matrix matched solution, fortified with standard of the derivative.

LOQ in apple: 0.05 mg/kg

Method in report P/B 1272 G:

Extraction with MeOH, analysis by LC-MS/MS (transition at 228 m/z → 187 m/z of dodine for primary quantification and a 2nd MRM transition 228 m/z → 60 m/z for qualitative confirmation).

LOQ in cherry: 0.01 mg/kg

Validated working range: 0.10 to 50 ng/mL (equivalent to 0.002 to 1 mg/Kg in cherry).

### 2.5.1.3.4 Ecotoxicology

#### Determination of dodine in feeding solutions for honey bee

██████████, 2017:

Feeding solution: Extraction with ice-cold (-20 °C) mixture of methanol/acetone (80/20; v/v), analysis by LC-MS/MS. LOQ: 0.026 g Dodine/L. Validated working range: 0.175 to 7.0 mg/L.

Stock solutions: dilution of the sample with methanol/acetone (80/20; v/v), analysis by HPLC-UV. LOD: 0.8 g Dodine/L. Validated working range: 0.431 to 5.17 mg/L.

██████████, 2016:

Feeding solution and stock solutions: Dilution of the sample with water/acetonitrile (80/20; v/v), analysis by HPLC-UV. LOQ (sugar solution): 0.0014 g Dodine/L. Validated working range: 0.132 - 4.82 mg/L in water/acetonitrile (80/20; v/v). Complete validation is required. Applicant informed that a new chronic bee study has been launched with new method of analysis.

#### Determination of dodine in water media

██████████, 2020:

Dilution with acetonitrile and acetonitrile/water (1/1, v/v), analysis by LC-MS/MS. LOQ: 0.0302 µg/L. Validated working range: 0.00506 – 0.504 µg test item/L.

██████████, 2008:

Dilution and analysis by LC-MS/MS. LOQ: 0.135 µg a.i./L (LOQ should be 1.98 µg a.i./L according to RMS assessment). Validated working range : 0.500 – 12.5 µg a.i./L.

██████████, 1989, 1990 and 1991

Determined spectrophotometrically after ion-pair partitioning into Chloroform containing 10% n-Butanol. LOQ: not determined. Validated working range: 0 to 10 ppm in water. The method is not accepted (Method not specific; calibration not correct; results not reliable).

██████████, 1992:

Extraction with ethyl acetate, derivatization with 1,1,1,5,5,5-hexafluoro-2,4-pentanedione, analysis by GC/NPD. LOQ: 0.0024 ng. Validated working range: 505 to 25.3 µg/L.

██████████, 2022:

Dilution of sample and analysis by UHPLC-MS. LOQ: 0.25 mg/mL, Validated working range: 0.300 to 4.80 µg/mL

#### **Determination of dodine in larvae and beetles of *Tenebrio molitor***

Extraction with MeOH, dilution and analysis by LC-MS/MS. LOQ: 0.3 mg/kg. Validated working range: 0.2 to 100 ng/mL equivalent to 0.08 to 100 mg/Kg.

#### **2.5.1.3.5 Physico-chemistry**

No individual studies available for methods for risk assessment in support of physical and chemical properties studies.

#### **2.5.1.3.6 Other studies (unclassified)**

##### **Determination of dodine in soil (report no EC-97-384):**

Extraction with methanolic solutions, derivatization with hexafluoroacetyl acetone (HFAA), analysis GC-MSD and calibration with matrix matched solution, fortified with standard of the derivative. LOQ: 10 ppb (ng/g) = 0.01 mg/kg. Validated working range: 20 – 150 ng/mL.

### **2.5.2 Methods for post control and monitoring purposes**

#### **2.5.2.1 Plants and plant products**

Residue definition for monitoring was set as follow in the EFSA Journal 2010; 8(6):1631, Conclusion on pesticides peer review of Dodine:

- For plants and plant products residues definition is Dodine.

Adequate analytical methods are available to monitor Dodine residues in High Water content plants (GC-MSD with LOQ of 0.05 mg/kg), Acidic Crop Matrices (LC/MS/MS with LOQ of 0.01 mg/kg), High Oil content plants (LC/MS/MS with LOQ of 0.01 mg/kg) and Dry Crop Matrices (LC/MS/MS with LOQ of 0.01 mg/kg).

#### **2.5.2.2 Food of animal origin**

Residue definition for monitoring was set as follow in the EFSA Journal 2010; 8(6):1631, Conclusion on pesticides peer review of Dodine:

- For food and animal origin: an analytical method for food of animal origin is not required due to the fact that no residue definition is proposed.

However, since the EFSA Journal 2010; 8(6):1631 the MRL for food and animal origin has now been set, therefore new methods are provided. Adequate analytical methods are available to monitor Dodine residues in Food/feed of animal origin, milk, muscle, egg and fat (LC/MS/MS with LOQ of 0.01 mg/kg). The efficiency of the extraction

procedure was not reported but it is not required, according to SANTE 2017/10632, Rev. 3, 2017, considering, that the expected residues in food of animal origin are very low (< 0.01 mg/kg) (please see Vol. 3, B.7.4).

- A new MRL is proposed for **honey**, 0.3 mg/kg for the NEU/SEU use *versus* the previous default value of 0.05 mg/kg. An adequate analytical method is available to monitor Dodine residues in honey: LC-MS/MS with a transition at 228 m/z → 186 m/z of dodine for primary quantification and a 2nd MRM transition (228 m/z → 60 m/z) for qualitative confirmation. LOQ of 0.01 mg/kg. **An ILV is required according to SANTE/2020/12830 rev. 2**

### 2.5.2.3 Soil

Residue definition for monitoring was set as follow in the EFSA Journal 2010; 8(6):1631, Conclusion on pesticides peer review of Dodine:

- For soil residues definition is Dodine.

Adequate analytical methods are available to monitor Dodine residues in soil (GC/MS with LOQ of 0.01 mg/kg and LC/MS/MS with LOQ of 0.01 mg/kg).

### 2.5.2.4 Water

Residue definition for monitoring was set as follow in the EFSA Journal 2010; 8(6):1631, Conclusion on pesticides peer review of Dodine:

- For water residues definition is Dodine.

Adequate analytical methods are available to monitor Dodine residues in surface water (LC/MS/MS with LOQ of 0.008 µg/L and LC/MS/MS with LOQ of 0.05 µg/L).

**ILV is required for drinking water.**

### 2.5.2.5 Air

Residue definition for monitoring was set as follow in the EFSA Journal 2010; 8(6):1631, Conclusion on pesticides peer review of Dodine:

- For air the residues definition is Dodine

Analytical methods are available to monitor Dodine residues in air (LC/MS/MS with LOQ 0.00850 mg/absorber (0.1xC-level)). Nevertheless the specificity was not demonstrated according to SANCO/825/00 rev.8.1 for monitoring since only one MS transition was validated. In addition the LOQ (0.0085 mg/absorber) of the method is not low enough to cover the trigger value of 0.00173 mg dodine / absorber. Therefore the validation of the method does not fully comply the requirements of the guidance SANTE/2020/12830 rev. 1, 2021 regarding specificity and LOQ and it is not adequately validated.

### 2.5.2.6 Body fluids and tissues

Residue definition for monitoring was set as follow in the EFSA Journal 2010; 8(6):1631, Conclusion on pesticides peer review of Dodine:

- For body fluids the residues definition is Dodine

But residue definition for body fluids and tissues was set as dodine and the metabolite hydroxy-dodecylguanidine in the current evaluation for renewal (please see Vol. 1, section 2.6.1.1).

Adequate analytical methods are available to monitor Dodine residues in tissues (liver) by LC/MS/MS with LOQ of 0.01 mg/kg.

In body fluids (human blood and urine) dodine is determined by LC/MS/MS with LOQ of 2 µg/L. A confirmatory method for dodine and the metabolite hydroxy-dodecylguanidine at the LOQ of 0.002 mg/kg in urine and blood is required. A confirmatory method for the metabolite hydroxy-dodecylguanidine at the LOQ of 0.005 mg/kg in liver is required.

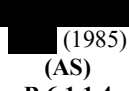

2.6 EFFECTS ON HUMAN AND ANIMAL HEALTH

2.6.1 Summary of absorption, distribution, metabolism and excretion in mammals [equivalent to section 9 of the CLH report template]

Table 17: Summary table of toxicokinetic studies

### 2.6.1.1 Short summary and overall relevance of the provided toxicokinetic information on the proposed classification(s)

A total of five studies have been submitted for the renewal of approval of the active substance dodine, only two were previously evaluated in the original DAR (2009), and three new studies (including the *in vitro* comparative metabolism study) have been submitted for the renewal process. In addition, an evaluation report with toxicokinetic calculations using the data from the ██████████ 1985 study was provided.

#### Oral route

- An *in vivo* single-and repeated dose study in rats was provided (Vol.3, AS, B.6.1.1.1). In this study, absorption, excretion, distribution and metabolism were assessed after oral (gavage) administration to Sprague-Dawley rats. The authors used a single low dose of 40 mg/kg bw, and a single high dose of 400 mg/kg bw. On the other hand, a multiple dose group based on 14 single oral daily doses (40 mg/kg bw) of non-labelled dodine followed by the 15<sup>th</sup> oral dose (40 mg/kg bw) of <sup>14</sup>C-dodine was tested. Dodine-derived radioactivity was eliminated within 120 h in both male and female rats. The major portion of the radioactivity in the single and multiple low oral dose (40 mg/kg bw) groups was eliminated in the first 48 h, almost equally in urine and feces for both sexes, whereas in the single high dose group, the excretion was slower than observed at low dose, but completed within 120 h.

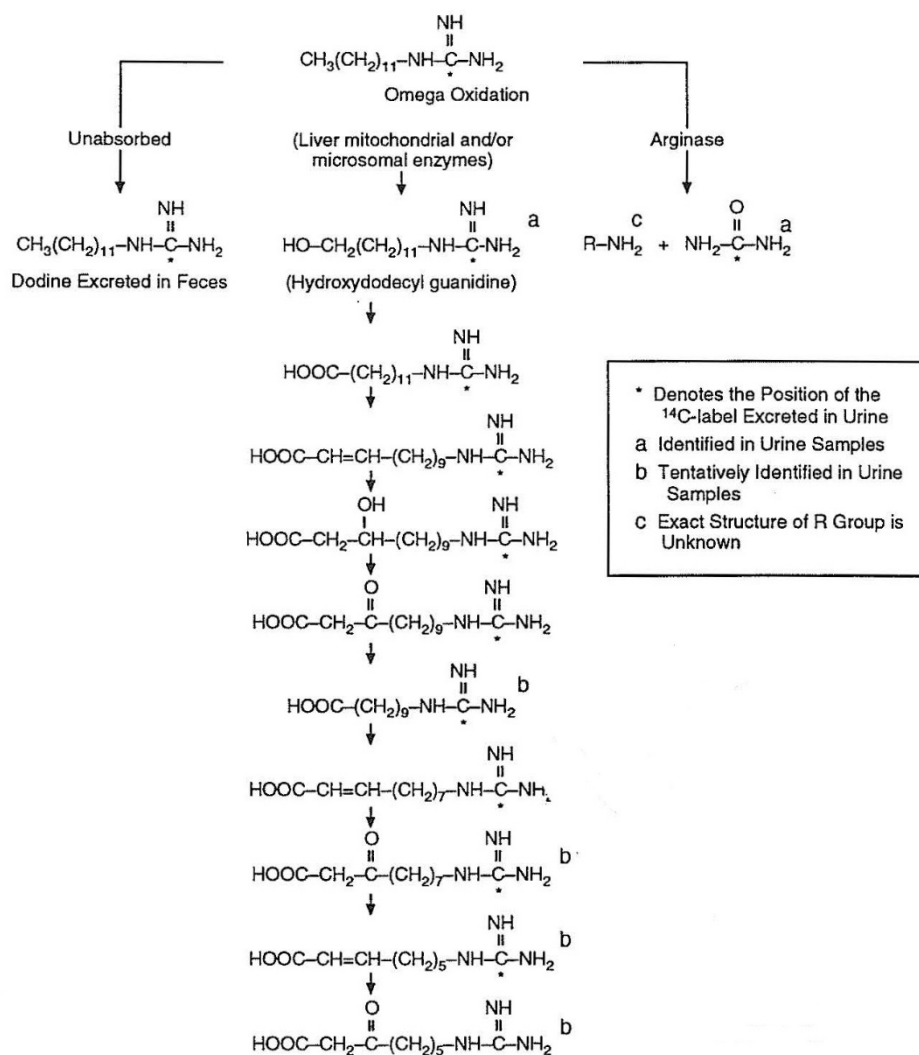

At 120 h, in the single dose groups, dodine-derived radioactivity recovered in urine was 42% and 43% for low and high dose groups, respectively; and in faeces 60% and 50% for low and high dose groups, respectively. Furthermore, <sup>14</sup>C-dodine elimination in multiple dose group was 45% and 56% in urine and feces, respectively, at 120 h. Faecal elimination (approx. 50-60% of the administered dose) was higher than urine excretion (40-45% of the administered dose) in all dose groups at 120 h. No relevant amounts of radioactivity were detected in blood and tissues. The recovery of radioactivity in all tissues together ranged from 0.67% to 3.33%, and the overall distribution pattern at 120 h was similar in both sexes of all dose groups. Oral absorption of <sup>14</sup>C-dodine in rats accounts for less than 50% (approx. 43.6% at 120 h after single dose of 40 mg/kg bw).

On the other hand, most of the dodine-derived radioactivity in the urine was eliminated as metabolites, where the parent compound was not detected. Four metabolites were mainly observed in urine, being hydroxy-dodecylguanidine, an omega-oxidation product, the major metabolite (up to 24% of dose). In faecal extracts, the parent compound was found to be the major component.

Because of the presence of the hydroxy dodecylguanidine (M2) and the other tentatively identified acids in the M4 peak, the author of the study postulated that, the metabolism of dodine follows a beta oxidation pathway similar to that of medium- or long-chain fatty acids. Upon entering the liver cell, dodine may be activated by formation of a CoA derivative. With the help of a carrier (similar to carnitine) it may be entering the mitochondrial matrix, and being oxidized by a sequence of reactions in which the alkyl chain of dodine is shortened by two carbon atoms at a time (beta oxidation). This series of reactions may also be catalyzed by a monooxygenase that requires NADPH, O<sub>2</sub>, and cytochrome P450.

The absorbed dodine probably enters the liver through the portal circulation and is metabolized to hydroxydodecylguanidine and other intermediate products with shorter chain lengths which are then eliminated through the urine. Urea may also be formed in the liver as a result of the action of arginase on dodine and/or one or more of its metabolites and eliminated through the urine.

Figure 2.6.1.1/1. Proposed metabolic pathway of dodine in Sprague-Dawley rats

- Another *in vivo* study tested the toxicokinetics of dodine in plasma after a single oral gavage administration in Sprague-Dawley rats (Vol.3, AS, B.6.1.1.2) at 40 mg/kg or 400 mg/kg bw. Dodine was rapidly absorbed, with  $T_{\max}$  values ranging from 2-4 hours. However,  $T_{\max}$  was 12 hours for low male dose group, but at  $t = 4$  already a peak in concentration data was observed, which could be related to the absorption phase. Some sex differences in toxicokinetics parameters were also appreciated within each tested group. In the low dose group,  $C_{\max}$  value of females (0.836 mg/kg bw) was 2-fold the males' value (0.417 mg/kg bw), whereas  $T_{\max}$  of males was 12 hours compared with the 4 h. in females. In the high dose group,  $T_{1/2}$  value of males (61 h.) was almost 2-fold the females' value (36 h.). On the other hand, clinical signs were observed in the high dose group after dodine single oral administration. Piloerection was observed in all animals, whereas other signs such as lethargy, hunched posture, chromodacryorrhoea, and mucous feces were observed throughout experiment.

- A recent *in vivo* study that tested the absorption, distribution and excretion of <sup>14</sup>C-dodine in Sprague-Dawley rats after a single oral dose of 5 mg/kg bw, was provided for the renewal process of dodine (Vol.3, AS, B.6.1.1.3). The present study showed that dodine-derived radioactivity was eliminated within 72 h in both male and female rats. Excretion of radioactivity via bile was a minor route of excretion. Excretion was rapid and almost complete (96%) within 48 h (34% urinary, 59% faecal and 3% bile). No relevant sex differences were appreciated. Regarding clinical signs after single oral administration, piloerection was observed in 50% of males (2/4) and 75% of females (3/4). Overall, oral absorption after <sup>14</sup>C- dodine administration in rats accounts for 39% for both sexes.

- Another *in vivo* study tested the absorption, distribution, metabolism and excretion of <sup>14</sup>C-dodine in Sprague-Dawley rats after oral (single dosing, 5 and 50 mg/kg bw, repeated dosing, 5 mg/kg bw) and intravenous administration (i.v, 5 mg/kg bw) (Vol.3, AS, B.6.1.1.4). Regarding plasma radioactivity levels, a peak was reached earlier after i.v. administration (30 and 5 min. for males and females, respectively), than observed after oral administration (~4 h for both sexes). On the other hand, after single oral dose (5 mg/kg bw), major portion of radioactivity excretion occurred in 24 h, at similar proportion in urine and feces, whereas after single i.v.

administration, excretion was observed mainly through urine at 24 h. At 96 h, radioactivity recovery was >90% for both oral and i.v. routes. No differences in excretion were recorded between males and females. Additionally, no relevant accumulation was observed in tissues, and <sup>14</sup>C recovery was low (~0.5%). Radioactivity remaining in the residual carcass was higher by intravenous injection (8%) compared to oral administration (0.6%). Analysis of the metabolites indicates that <sup>14</sup>C-dodine was rapidly metabolised to a number of unidentified polar components, which were chromatographically dissimilar to dodine, dodecylamine and dodecylurea.

-A toxicokinetic report that re-analysed previous data from [REDACTED] study (Vol. 3, B.6.1.1.4), has also been provided (Vol. 3, B.6.1.1.5). This review used the available data with the aim to calculate toxicokinetic parameters such as bioavailability (F), that original authors did not calculate. Due to this report is based on the B.6.1.1.4 study data, and such study presented methodological deviations, the B.6.1.1.5 ([REDACTED], 2020) study is hence considered as supporting information, and the (F) and other toxicokinetic parameters could be taken such as rough estimation. The current report showed that T<sub>max</sub> value was shorter (5 and 15 min. for females and males, respectively) after i.v. administration than oral (ranged from 4 to 8 h for both sexes) administration. The AUC<sub>24</sub> values increased approximately proportionately to the dose increment after a single oral dose of <sup>14</sup>C-dodine. On the other hand, C<sub>max</sub> values were higher in the i.v. group than in the single oral low dose group at similar dose (5 mg/kg bw). An estimated oral bioavailability of radioactivity following single doses value was in the range 36.1- 43.4%.

Comparative metabolism

-An *in vitro* comparative study has been presented for the renewal purpose of dodine (Vol. 3, B.6.1.1.6). This study evaluated the metabolic profile of dodine, and identified the main metabolites formed using rat, dog and human liver microsomes as test system. No human specific metabolites were detected as the four radioactivity peaks detected (including dodine peak) in human liver microsomes were also detected in at least one of the animal species. Of these, three of them were found in the three species tested, and one metabolite was mainly detected in human (>4-fold). The metabolism of <sup>14</sup>C-dodine included oxidations and desaturations.

Other routes

No studies of dodine by dermal or inhalation routes have been submitted. There is no concern for toxicity following dermal exposure to dodine as acute dermal toxicity is expected low compared to acute toxicity following oral exposure. As for the inhalation route, dodine is not volatile (vapour pressure: < 5.49 x 10<sup>-6</sup> Pa at 50°C). Therefore, no studies are required using dermal or inhalation routes of exposure.

Residue definition for body fluids and tissues

Considering the available information, residues in body fluids it could be applied to active substance dodine and the metabolite hydroxy-dodecylguanidine identified as a major metabolite in urine of rats exposed to dodine.

**2.6.2 Summary of acute toxicity**

**2.6.2.1 Acute toxicity - oral route [equivalent to section 10.1 of the CLH report template]**

Table 18: Summary table of animal studies on acute oral toxicity

| Method, guideline, deviations if any  | Species, strain, sex, no/group                                 | Test substance, dose levels, duration of exposure   | Value LD <sub>50</sub>  | Reference       |         |       |          |     |       |       |        |     |       |       |        |      |       |       |        |  |

**2.6.2.1.1 Short summary and overall relevance of the provided information on acute oral toxicity**

All the available acute oral toxicity studies performed with dodine technical were included and assessed in the previous DAR (2009). Two of the three animal studies were performed according to guidance test methods and are considered acceptable: one in rats (██████████ 1999; B.6.2.1.1) and the other in mice (██████████, 2008; B.6.2.1.2). The LD<sub>50</sub> values obtained in these studies were 817 mg/kg bw for female rats and 1354 mg/kg bw for female mice.

The last study in mice (██████████ 1985; B.6.2.1.3) is considered supportive information, since it was performed as a range-finding study, to determine the maximum dose level of dodine that does not cause mortality in a subsequent mutagenicity study. Selected doses for the study were 250 and 500 mg/kg bw based on the available data at the moment of the study, that suggested an oral LD<sub>50</sub> value for mice between 500 and 1000 mg/kg bw. No deaths occurred and therefore, the resulting LD<sub>50</sub> value of this study is > 500 mg/kg bw, supporting the results obtained in the other study in mice (LD<sub>50</sub> = 1354 mg/kg bw).

Harmonized classification and labelling of dodine is listed in Annex VI of Regulation (EC) No. 1272/2008 (modified for the last time by Commission Directive 98/73/EC of 18<sup>th</sup> September 1998). Classification regarding acute oral toxicity is included as Acute (oral) toxicity, category 4 (Acute Tox. 4\*; H302).

**2.6.2.1.2 Comparison with the CLP criteria regarding acute oral toxicity**

The lowest oral LD<sub>50</sub> value obtained for dodine was 817 mg/kg bw, obtained in the study in rats (██████████ 1999; B.6.2.1.1). This value is between the threshold values of 300 and 2000 mg/kg bw established in Regulation (EC) No. 1272/2008 for classification of a substance as Acute (oral) Toxicity in category 4 (Acute Tox.4; H302).

**2.6.2.1.3 Conclusion on classification and labelling for acute oral toxicity**

According to the criteria under Regulation (EC) No. 1272/2008, dodine is classified as **acute (oral) toxicity, category 4, Acute Tox. 4 (H302)** with an ATE (oral) = **817 mg/kg bw** based on the lowest LD<sub>50</sub> obtained in the available acute oral toxicity studies.

**2.6.2.2 Acute toxicity - dermal route [equivalent to section 10.2 of the CLH report template]**

**2.6.2.2.1 Short summary and overall relevance of the provided information on acute dermal toxicity**

Animal data provided to address the acute dermal toxicity of dodine consisted in one acceptable study (██████████ 1999b; B.6.2.2), which was already assessed and accepted in de previous DAR (2009). This study complies with the guidance test methods and no deviations from the guideline were observed.

The resulting LD<sub>50</sub> of this study is > 5000 mg/kg bw for male and female rats.

Harmonized classification and labelling of dodine is listed in Annex VI of Regulation (EC) No. 1272/2008 (modified for the last time by Commission Directive 98/73/EC of 18<sup>th</sup> September 1998) and no classification regarding acute dermal toxicity is included.

**2.6.2.2.2 Comparison with the CLP criteria regarding acute dermal toxicity**

The LD<sub>50</sub> of dodine is greater than 5000 mg/kg bw (according to the study of ██████████ 1999b; B.6.2.2), which is above the threshold value of 2000 mg/kg bw established in Regulation (EC) No. 1272/2008 for triggering acute dermal toxicity classification.

**2.6.2.2.3 Conclusion on classification and labelling for acute dermal toxicity**

Data available indicates that dodine does not require classification for acute dermal toxicity.

**2.6.2.3 Acute toxicity - inhalation route [equivalent to section 10.3 of the CLH report template]**

**2.6.2.3.1 Short summary and overall relevance of the provided information on acute inhalation toxicity**

Animal data provided to address the acute toxicity of dodine by inhalation consisted in one acceptable study (█ 1999; B.6.2.3), which was already assessed and accepted in de previous DAR (2009). This study complies with the guidance test methods and no relevant deviations from the guideline were observed. The resulting 4-hour LC<sub>50</sub> value of this study is 0.44 mg/L for female Sprague-Dawley rats (nose-only exposure).

Harmonized classification and labelling of dodine is listed in Annex VI of Regulation (EC) No. 1272/2008 (modified for the last time by Commission Directive 98/73/EC of 18<sup>th</sup> September 1998). No classification regarding acute inhalation toxicity is included.

**2.6.2.3.2 Comparison with the CLP criteria regarding acute inhalation toxicity**

Dodine LC<sub>50</sub> value, obtained after 4-hour nose-only exposure in rats, is 0.44 mg/L (█ 1999; B.6.2.3). This value is between the threshold values of 0.05 and 0.5 mg/L (for dusts and mists) established in Regulation (EC) No. 1272/2008 for classification of a substance as Acute (inhalation) Toxicity in category 2 (Acute Tox. 2; H330).

**2.6.2.3.3 Conclusion on classification and labelling for acute inhalation toxicity**

Based on the available data on dodine, and according to the criteria under Regulation (EC) No. 1272/2008, this active substance is classified as **acute (inhalation) toxicity, category 2, Acute Tox. 2 (H330)** with an **ATE (inhalation) of 0.44 mg/L (dust/mist)** based on the lowest LC<sub>50</sub> obtained in females in the available acute inhalation toxicity study in rats.

2.6.2.4 Skin corrosion/irritation [equivalent to section 10.4 of the CLH report template]

2.6.2.4.1 Short summary and overall relevance of the provided information on skin corrosion/irritation

Animal data provided to address the acute skin irritation properties of dodine consisted in one acceptable study (1999c; B.6.2.4), which was already assessed and accepted in de previous DAR (2009). This study complies with the guidance test methods and no relevant deviations from the guideline were observed.

Under the conditions of the study, dodine technical caused inflammation in the application site in the form of erythema (reaching grades 2 and 3) that lasted in two of the three animals until the end of the 14-day observation period (not reversible).

Moreover, in the acute toxicity study by dermal route (██████████ 1999b; B.6.2.2), erythema, desquamation and exfoliation were observed in several animals at the end of the 14-day observation period, confirming the non-reversibility of the skin lesions provoked by the substance.

Harmonized classification and labelling of dodine is listed in Annex VI of Regulation (EC) No. 1272/2008 (modified for the last time by Commission Directive 98/73/EC of 18th September 1998). Classification regarding skin corrosion/irritation is included as Skin irritation, category 2 (Skin Irrit. 2; H315).

**2.6.2.4.2 Comparison with the CLP criteria regarding skin corrosion/irritation**

According to the current EU Criteria (Regulation (EC) No 1272/2008), classification as skin irritant is required if inflammation persists to the end of the observation period in at least 2 animals.

Available animal data on dodine described erythema (grade 1) and desquamation that lasted until the end of the observation period in two of the three animals of the skin corrosion/irritation study (██████████ 1999c; B.6.2.4), together with erythema (grades 1 and 4), desquamation and exfoliation in several animals of the acute dermal toxicity study by dermal route (██████████ 1999b; B.6.2.2).

Therefore, the assessed information confirms the actual classification of dodine in Annex VI of Regulation (EC) No 1272/2008 as skin irritant category 2 and, therefore, no modification of this classification is proposed.

**2.6.2.4.3 Conclusion on classification and labelling for skin corrosion/irritation**

No modification of the actual classification of dodine as **skin irritation, category 2 (Skin Irrit. 2, H315)** is proposed.

**2.6.2.5 Serious eye damage/eye irritation [equivalent to section 10.5 of the CLH report template]**

Table 30: Summary table of animal studies on serious eye damage/eye irritation

**2.6.2.5.1 Short summary and overall relevance of the provided information on serious eye damage/eye irritation**

Animal data provided to address the acute eye irritation properties of dodine consisted in one acceptable study (██████████ 1999d; B.6.2.5), which was already assessed and accepted in de previous DAR (2009). This study complies with the guidance test methods and no relevant deviations from the guideline were observed.

Under the conditions of the study no reversibility of the lesions were observed, with maximum scores noted for corneal opacity (4), iris lesion (2), conjunctival redness (3) and chemosis (4) even 7 days after instillation. Moreover, corneal neovascularization was also noted at day 7, confirming the serious eye damage caused by dodine in the rabbit.

Harmonized classification and labelling of dodine is listed in Annex VI of Regulation (EC) No. 1272/2008 (modified for the last time by Commission Directive 98/73/EC of 18th September 1998). Classification regarding skin corrosion/irritation is included as Eye irritation, category 2 (Eye Irrit. 2; H319).

**2.6.2.5.2 Comparison with the CLP criteria regarding serious eye damage/eye irritation**

According to the current EU Criteria (Regulation (EC) No 1272/2008), classification of substances within hazard class Category 1 (serious eye damage), includes persistent lesions (those which are not fully reversible within an observation period of normally 21 days).

Available animal data on dodine (██████████ 1999d; B.6.2.5) described maximum scores for corneal opacity (4), iris lesion (2), conjunctival redness (3) and chemosis (4) until day 7, when the study was finalised. These scores were maintained from 24 hours post-instillation.

Mean values could not be obtained for corneal and iris lesions since at 24 and 48 hours after instillation, it was not possible to determine these grades due to severe chemosis (and maximum scores were applied).

Moreover, the grades of corneal opacity and iritis remaining by day 7 are considered severe in the three rabbits, since these scores (4 and 2, respectively) exceed the value established as CLP criteria (mean 24/48/72 h values ≥ 3 for corneal opacity and/or >1.5 for iritis) for classification of substances as Category 1.

Altogether, the assessed information suggests the actual classification of dodine in Annex VI of Regulation (EC) No 1272/2008 (as eye irritant category 2) is underestimated and, therefore, classification in a higher category (serious eye damage, category 1) is proposed.

**2.6.2.5.3 Conclusion on classification and labelling for serious eye damage/eye irritation**

Based on the available data on dodine, and according to the criteria under Regulation (EC) No. 1272/2008, classification of this active substance in category 2 should be modified to: serious eye damage, category 1, Eye Dam. 1 (H318).

2.6.2.6 Respiratory sensitisation [equivalent to section 10.6 of the CLH report template]

Table 33: Summary table of animal studies on respiratory sensitisation

2.6.2.6.1 Short summary and overall relevance of the provided information on respiratory sensitisation

No data available for dodine.

Harmonized classification and labelling of dodine is listed in Annex VI of Regulation (EC) No. 1272/2008 (modified for the last time by Commission Directive 98/73/EC of 18<sup>th</sup> September 1998) and no classification regarding respiratory sensitization is included.

2.6.2.6.2 Comparison with the CLP criteria regarding respiratory sensitisation

No data available for dodine.

2.6.2.6.3 Conclusion on classification and labelling for respiratory sensitisation

In the absence of any data, no classification for respiratory sensitisation can be drawn for dodine.

2.6.2.7 Skin sensitisation [equivalent to section 10.7 of the CLH report template]

**2.6.2.7.1 Short summary and overall relevance of the provided information on skin sensitisation**

Animal data provided to address the skin sensitization properties of dodine consisted in one acceptable study (██████████ 1999; B.6.2.6), which was already assessed and accepted in de previous DAR (2009). This study complies with the guidance test methods and, although skin reactions after induction applications were not recorded, sodium lauryl sulfate (10% w/w) in vaseline was applied the previous day and no relevant deviations from the guideline were observed.

No skin sensitization responses were provoked by dodine under the conditions of the study.

Harmonized classification and labelling of dodine is listed in Annex VI of Regulation (EC) No. 1272/2008 (modified for the last time by Commission Directive 98/73/EC of 18th September 1998) and no classification regarding skin sensitization is included.

**2.6.2.7.2 Comparison with the CLP criteria regarding skin sensitisation**

Available animal data showed negative results in an acceptable maximization (Magnusson and Kligman) study in guinea pigs.

**2.6.2.7.3 Conclusion on classification and labelling for skin sensitisation**

Data available indicates that dodine does not require classification for skin sensitization.

**2.6.2.8 Phototoxicity**

Table 39: Summary table of studies on phototoxicity

| Method, guideline, deviations <sup>1</sup> if any | Test substance | Dose levels duration of exposure | Results | Reference |
|---|----------------|----------------------------------|---------|-----------|
| No data available.                                |                |                                  |         |           |

Table 40: Summary table of human data on phototoxicity

| Type of data/report | Test substance | Relevant information about the study (as applicable) | Observations | Reference |
|---------------------|----------------|--|--------------|-----------|
| No data available.  |                |  |              |           |

Table 41: Summary table of other studies relevant for phototoxicity

| Type of study/data | Test substance | Relevant information about the study (as applicable) | Observations | Reference |
|--------------------|----------------|--|--------------|-----------|
| No data available. |                |  |              |           |

No phototoxicity study with dodine was provided. However, this testing is not required by Regulation (EU) No 283/2013, since the results of UV/Visible spectroscopy performed with the active substance dodine showed no absorption with wavelength > 290 nm.

**2.6.2.9 Aspiration hazard [equivalent to section 10.13 of the CLH report template]**

Table 42: Summary table of evidence for aspiration hazard

| Type of study/data | Test substance | Relevant information about the study (as applicable) | Observations | Reference |
|--------------------|----------------|--|--------------|-----------|
| No data available  |                |  |              |           |

**2.6.2.9.1 Short summary and overall relevance of the provided information on aspiration hazard**

No evidence of aspiration hazard of dodine was found in the provided data.

Harmonized classification and labelling of dodine is listed in Annex VI of Regulation (EC) No. 1272/2008 (modified for the last time by Commission Directive 98/73/EC of 18<sup>th</sup> September 1998) and no classification regarding aspiration hazard.

**2.6.2.9.2 Comparison with the CLP criteria regarding aspiration hazard**

Dodine is presented in a solid (particulate/powder) form. According to CLP Regulation, “Although the definition of aspiration in section 3.10.1.2 includes the entry of solids into the respiratory system, classification according to point (b) in Table 3.10.1 for Category 1 is intended to apply to liquid substances and mixtures only”. Hence, this point does not apply for dodine.

Besides, according to point (a) of Table 3.10.1 of CLP Regulation, a substance can be classified for aspiration toxicity based on reliable and good quality human evidence. Dodine is not a hydrocarbon compound and no data associated with this hazard class have been reported in humans for dodine.

Taking into account points (a) and (b) of classification criteria for aspiration toxicity included in Table 3.10.1 of CLP Regulation, criteria for classification for this hazard class are not fulfilled for dodine.

**2.6.2.9.3 Conclusion on classification and labelling for aspiration hazard**

No classification proposed based on data conclusive but not sufficient for classification.

2.6.2.10 Specific target organ toxicity-single exposure (STOT SE) [equivalent to section 10.11 of the CLH report template]

**2.6.2.10.1 Short summary and overall relevance of the provided information on specific target organ toxicity – single exposure (STOT SE)**

Specific target organ toxicity (single exposure) is defined as specific, non-lethal target organ toxicity arising from a single exposure to a substance or mixture. Relevant information for STOT SE is covered by acute toxicity studies in form of clinical observations and macroscopic and microscopic pathological examination that can reveal hazards that may not be life-threatening but could indicate functional impairment. Effects of other single dose studies or repeated dose studies (first dosing effects) are also considered for STOT SE.

During the analysis of the classification of dodine as STOT SE, effects potentially relevant for STOT SE have been found in acute toxicity studies and genotoxicity/germ cell mutagenicity studies (from sections 2.6.2 and 2.6.4, respectively).

In the acute oral toxicity study in rats (B.6.2.1.1), the effects observed relevant for STOT SE were hypoactivity in all rats from 761 mg/kg bw (reversible in surviving animals), impaired muscle coordination in some animals at 1285 mg/kg bw and penis prolapse from 761 mg/kg bw.

In the acute oral toxicity study in female mice (B.6.2.1.2), the effects observed relevant for STOT SE were clinical signs like little noise at breathing with reversibility at the next day from 970 mg/kg bw, decreased spontaneous activity in all mice from 1290 mg/kg bw and decreased Preyer’s reflex and righting reflex from 1290 mg/kg bw.

In the acute inhalation toxicity study in rats (B.6.2.3), the effects relevant for STOT SE were found among clinical signs, organs’ weights and gross pathology parameters. Brown staining around snout and/or jaws was observed from 0.25 mg/L, matted fur from 0.34 mg/L, wet fur from 0.25 mg/mL, pilo-erection at 0.51 mg/L, gasping from 0.25 mg/L, cold body to touch: at 0.51 mg/L, lethargy from 0.34 mg/L and ataxia at 0.34 mg/L. Lungs weight increased from 0.34 mg/mL, liver weight decreased from 0.25 mg/mL and kidney weight decreased from 0.25 mg/mL. Increased incidence of congestion in lung lobes was observed from 0.34 mg/mL and in intestines from 0.51 mg/mL. Furthermore, the incidence of enlarged heart was incremented in females from 0.51 mg/mL.

In an in vivo micronucleus test (B.6.4.2.1-02), a dose-range finding study and a main study were carried out. In the dose-range finding study, no effects were seen immediately after dosing. 41 hours after dosing, some mice from 387.5 mg/kg bw/day died and the remaining had rough hair coats. Prior to euthanasia, all remaining mice from 387.5 mg/kg bw were languid and with rough hair coats. In the main micronucleus study, neither effects immediately after dosing were reported. Prior to the 48-hour and 72-hour harvests, one remaining male showed distended abdomen from 200 and 400 mg/kg bw, respectively.

Prior to the 72-h harvest, 1 ♂ at 400 mg/kg bw with distended abdomen.

**2.6.2.10.2 Comparison with the CLP criteria regarding STOT SE (specific target organ toxicity-single exposure)**

STOT SE 1 and 2

STOT-SE Category 1 and 2 is assigned on the basis of findings of ‘significant’ or ‘severe’ toxicity. In this context

‘significant’ means changes which clearly indicate functional disturbance or morphological changes which are toxicologically relevant. ‘Severe’ effects are generally more profound or serious than ‘significant’ effects and are of a considerably adverse nature with significant impact on health. Both factors have to be evaluated by weight of evidence and expert judgement.

Effects in the range of STOT SE 1 (guidance value for classification by inhalation: ≤ 1 mg/L/4h) were observed in the acute inhalation study in rats. They were observed mainly at doses close to the LC<sub>50</sub> and they were covered by the classification proposal for dodine as Acute (inhalation) Tox. 2 (H330).

Effects in the range of STOT SE 2 (guidance value for classification by oral, ≤ 2000 mg/kg bw and >300 mg/kg bw) were observed in acute oral studies in rats and mice and in an *in vivo* micronucleus test. They were observed mainly at doses close to the LD<sub>50</sub> (therefore, they were covered by the classification proposal for dodine as Acute (oral) Tox. 4; H302) and/or did not indicate the presence of a clear target organ.

Therefore, dodine does not require classification for STOT SE 1 or 2.

**STOT SE 3**

STOT SE 3 includes narcotic effects and respiratory tract irritation. These are target organ effects for which a substance does not meet the criteria to be classified in Categories 1 or 2.

Although some of the acute effects observed after the administration of dodine could be considered as narcotic effects (i.e. hypoactivity, loss of reflex, lethargy or ataxia) and respiratory tract irritation signs (congestion of the lung lobes), they were all observed only at doses covered by the classification proposal for dodine as Acute Tox. (H302 and H330).

Therefore, dodine does not require classification for STOT SE 3.

**2.6.2.10.3 Conclusion on classification and labelling for STOT SE (specific target organ toxicity-single exposure)**

Dodine does not require classification for STOT SE according to CLP Regulation.

**2.6.3 Summary of repeated dose toxicity (short-term and long-term toxicity) [section 10.12 of the CLH report]**

**2.6.3.1 Specific target organ toxicity-repeated exposure (STOT RE) [equivalent to section 10.12 of the CLH report template]**

**2.6.3.1.1 Short summary and overall relevance of the provided information on specific target organ toxicity – repeated exposure (short-term and long-term toxicity)**

The above-mentioned short-term studies were already considered in the DAR and have been re-assessed according to current guidelines. Long-term, multigeneration, developmental and immunotoxicity studies have also been included in this evaluation of effects relevant for STOT RE.

**Studies in rats:**

In the first 28-day oral study in rats (B.6.3.1.1, AS), performed by gavage administration of dodine, mortality was reported in all animals at 200 mg/kg bw/day, in 4/10 females at 100 mg/kg bw/day and in one female at 75 mg/kg bw/day, and respiratory problems, salivation and yellow staining of the fur were observed from 75 mg/kg bw/day. A decrease in the bodyweight was observed in males from 75 mg/kg bw/day and in females from 100 mg/kg bw/day. The bodyweight gain and food consumption were reduced in both sexes from 75 mg/kg bw/day. Regarding

haematology parameters, white blood cells and segmented neutrophils levels were increased and lymphocyte percentage was reduced in both sexes at 100 mg/kg bw/day. Red cell distribution width was affected, being increased in males at 100 mg/kg bw/day. An increment in alanine aminotransferase level was observed in both sexes from 75 mg/kg bw/day, while at 100 mg/kg bw/day the relative-to-body liver weight was incremented in females. The relative-to-body lung weight was increased in males at 100 mg/kg bw/day, in which also dark, depressed and pale areas were reported. The relative-to-body adrenal weight in males and the relative-to-body and relative-to-brain adrenals weights in females were increased at 100 mg/kg bw/day. Haemorrhage was seen in adrenals from rats at 200 mg/kg bw/day (examination not extended to animals of lower dose groups). The incidence of microscopical findings was increased in stomach from 75 mg/kg bw/day in both sexes.

In this study, a NOAEL was not derived, but a **LOAEL of 75 mg/kg bw/day** was set based on the mortality in females, the increased incidence of several clinical signs in both sexes, the reduction of bodyweight in males, the reduction in bodyweight gain in both sexes, the decrease in food consumption in both sexes and the increase in alanine aminotransferase levels in both sexes, observed at this dose which was the lower tested.

Significant effects in haematology in both sexes at 100 mg/kg bw/day are within the range for STOT RE 2 category (>30 mg/kg bw/day and ≤ 300 mg/kg bw/day, applying Haber's rule) but the pattern of adversity is not sufficient to trigger STOT RE classification.

Significant effects in clinical biochemistry related to liver in both sexes at 75 mg/kg bw/day and effects in liver in females at 100 mg/kg bw/day are within the range for STOT RE 2 category (>30 mg/kg bw/day and ≤ 300 mg/kg bw/day, applying Haber's rule) but the pattern of adversity is not sufficient to trigger STOT RE classification.

Effects in lungs in males at 100 mg/kg bw/day are within the range for STOT RE 2 category (>30 mg/kg bw/day and ≤ 300 mg/kg bw/day, applying Haber's rule) but the pattern of adversity is not sufficient to trigger STOT RE classification.

Effects in adrenals in both sexes at 100 mg/kg bw/day are within the range for STOT RE 2 category (>30 mg/kg bw/day and ≤ 300 mg/kg bw/day, applying Haber's rule) but the pattern of adversity is not sufficient to trigger STOT RE classification.

In the second 28-day oral study in rats (B.6.3.1.2, AS), performed by administration of dodine in diet, no death was reported. A decrease in the bodyweight was observed in both sexes at 1000 ppm. The bodyweight gain was reduced in males treated from 750 ppm and in females from 500 ppm, and food consumption was reduced in both sexes from 750 ppm. A decrease in the alanine aminotransferase levels was observed in females treated at 1000 ppm of dodine. The absolute and relative-to-brain weights of kidneys were reduced in both sexes at 1000 ppm. At the same dose, the incidence of mineralization of the cortico-medullary junction in females and, only slightly, the incidence of fibrosis in kidneys in both sexes were incremented. An increase in the relative-to-body lung weight in females was revealed at 1000 ppm, in which also dark areas were reported.

In this study, a NOAEL was not derived, but a **LOAEL of 500 ppm (equivalent to 47 mg/kg bw/day)** was set based on the reduction of the bodyweight gain in females observed from the lower dose tested.

Significant effects in clinical biochemistry related to liver in females at 1000 ppm (equivalent to 92 mg/kg bw/day) are within the range for STOT RE 2 category (>30 mg/kg bw/day and ≤ 300 mg/kg bw/day, applying Haber's rule) but the pattern of adversity is not sufficient to trigger STOT RE classification.

Effects in kidneys in both sexes at 1000 ppm (equivalent to 87 and 92 mg/kg bw/day in males and females, respectively) are within the range for STOT RE 2 category (>30 mg/kg bw/day and ≤ 300 mg/kg bw/day, applying Haber's rule) but the pattern of adversity is not sufficient to trigger STOT RE classification.

Effects in lungs in females at 1000 ppm (equivalent to 92 mg/kg bw/day) are within the range for STOT RE 2 category (>30 mg/kg bw/day and ≤ 300 mg/kg bw/day, applying Haber's rule) but the pattern of adversity is not sufficient to trigger STOT RE classification.

In the third 28-day oral study in rats (B.6.3.1.3, AS), performed by administration of dodine with diet, the bodyweight gain was reduced in both sexes at 800 ppm and the food consumption was reduced in males at the same dose. Moreover, decreases in the absolute and relative-to-body liver weights in females were observed at 800 ppm. The **NOAEL** was set at 200 ppm (equivalent to **17.66 mg/kg bw/day**), based on the reduction of the bodyweight gain in both sexes, the reduction of food consumption in males and the decrease in the absolute and relative-to-body liver weight in females observed at 800 ppm.

Effects in liver in females at 800 ppm (equivalent to 76.71 mg/kg bw/day) are within the range for STOT RE 2 category (>30 mg/kg bw/day and ≤ 300 mg/kg bw/day, applying Haber's rule) but the pattern of adversity is not sufficient to trigger STOT RE classification.

In a 7-day and 28-day, gut motility oral toxicity study in rats (B.6.3.1.4, AS), dodine administered in diet caused a reduction in the bodyweight gain in both sexes at 800 ppm.

A NOAEL was not derived. No effects relevant for STOT RE were found in this study.

In a 90-day oral dietary toxicity study in rats (B.6.3.2.1., AS), dodine administration in diet caused a reduction in the bodyweight gain in both sexes and a decrease in the food consumption in females at 800 ppm. Also at 800 ppm,

an increase in the percentage of neutrophils in males and a decrease in the levels of alanine transaminase in females were observed.

The **NOAEL** of this study was set at 200 ppm (equivalent to **14.09 mg/kg bw/day**), based on decreased bodyweight gain in both sexes, the decrease in food consumption in females, increment in neutrophils in males and the decrease in alanine transaminase in females observed at 800 ppm.

Significant effects in haematology in males at 800 ppm (equivalent to 55.84 mg/kg bw/day) are within the range for STOT RE 2 category (>10 mg/kg bw/day and ≤ 100 mg/kg bw/day) but the pattern of adversity is not sufficient to trigger STOT RE classification.

Significant effects in clinical biochemistry related to liver in females at 800 ppm (equivalent to 60.44 mg/kg bw/day) are within the range for STOT RE 2 category (>10 mg/kg bw/day and ≤ 100 mg/kg bw/day) but the pattern of adversity is not sufficient to trigger STOT RE classification.

In a 90-day oral gavage toxicity study in rats (B.6.3.2.2., AS), dodine administration caused a reduction in the leukocyte count in females and increments of bilirubin and aspartate amino transferase levels in males at 20 mg/kg bw/day.

A **NOAEL** was not set for this study because of the absence of relevant information about the methodology and because most of the data were not shown. Also for these reasons, none of the effects reported were considered relevant for the decision on STOT RE classification.

In a 100-day oral dietary toxicity study in rats (B.6.3.2.3., AS), dodine administration caused a reduction in bodyweight gain and food consumption in males at 270 mg/kg bw/day and in females at 310 mg/kg bw/day.

A **NOAEL** was not set for this study because of the absence of relevant information about the methodology and because most of the data were not shown. For these reasons also, none of the effects reported were considered relevant for the decision on STOT RE classification.

In a 28-day dermal study in rats (B.6.3.4.1.1, AS), treatment of rats with dodine caused dermal irritation on application site from 50 mg/kg bw/day. Effects on treated skin were also evident during gross pathology and histopathology examinations from 125 mg/kg bw/day. Bodyweight gain was decreased in males from 125 mg/kg bw/day.

**Systemic NOAEL** for this dermal study was set at 50 mg/kg bw/day dose (equivalent to **35.7 mg/kg bw/day**, considering the 5-day per week administration), based on the decreased bodyweight gain in males from 125 mg/kg bw/day. A **NOAEL** for local effects could not be derived and a **LOAEL for skin local effects** was set at 50 mg/kg bw/day dose (equivalent to **35.7 mg/kg bw/day**, considering the 5-day per week administration), based on dermal irritation findings found on application sites in both sexes.

In conclusion, there were not effects relevant for STOT RE in this study.

A 21-day dermal study in rats (B.6.3.4.1.2, AS) was provided. This study was not considered acceptable, because it did not test dodine and furthermore, the substance tested was reported to be CT-334-87 (1-dodecylguanidinium hydrochloride) and it was not adequately characterised.

In the 2-year oral study in rats (B.6.5.1, AS), the **NOAEL** for toxicity was considered to be 400 ppm (equivalent to 20.34 and 26.5 mg/kg bw/day for males and females, respectively), based on clinical signs in males, decreased bodyweight in both sexes and food consumption in both sexes at 800 ppm (equivalent to **41.93 and 53.5 mg/kg bw/day** for males and females, respectively). A decrease in white blood cells and in lymphocytes was observed in males at 41.9 mg/kg bw/day. Effects were clearly above the cut-off value for STOT RE 2 after a 106-week period (≤ 12.3 mg/kg bw/day).

A second 2-year oral study in rats (B.6.5.3, AS), was available, but in this study the level of reporting was very limited. A **NOAEL** was not set.

In a two-generation study in rats (B.6.6.1.1, AS), parental **NOAEL** was set at 200 ppm (equivalent to 13.14 and 15.6 mg/kg bw/day for males and females, respectively) based on decreased bodyweights and increased relative adrenal weight in F<sub>1</sub> parents observed at 400 ppm (equivalent to **26.2 and 31.2 mg/kg bw/day** for males and females, respectively). Developmental **NOAEL** was derived at 200 ppm (equivalent to 13.14/15.6 mg/kg bw/day for males and females, respectively) based on decreased pup weights in F<sub>1</sub> and F<sub>2</sub> generations observed at 400 ppm (equivalent to 26.2/31.2 mg/kg bw/day for males and females, respectively).

Relative left adrenal weight was increased in F<sub>1</sub> parental females from 400 ppm. Absolute left kidney weight was decreased in F<sub>2</sub> male pups from 400 ppm. In F<sub>2</sub> generation at 800 ppm, the absolute spleen weight was reduced at 800 ppm in male and female pups and the absolute thymus weight was decreased in female pups.

None of these effects were considered enough for STOT RE 2 classification.

In a dose range finding developmental study in rats (B.6.6.2.1, AS), the maternal toxicity NOAEL was 50 mg/kg bw/day based on decreased bodyweight gain and food consumption observed at **100 mg/kg bw/day**, and developmental toxicity NOAEL was set at 100 mg/kg bw/day based on the absence of effects. One dam died at 100 mg/kg bw/day. An increase in the kidney incidences (pelvic dilatation and enlarged; 30%) and ureters (dilatation; 20%) was observed at 100 mg/kg bw/day. Moreover, one dam at 100 mg/kg bw/day exhibited alterations consistent with a long-standing partial obstruction in the lower urinary tract (epithelial hyperplasia and chronic inflammation of the urinary bladder; ureters inflammation; pelvic dilatation and inflammation, together with nephritis in the kidney; and hyperplasia of the lumbar lymph node). These findings could have been caused by a small calculus in the bladder or urethra, which might have been voided some time before death. None of the effects observed were considered enough for STOT RE 2 classification.

In a developmental study in rats (B.6.6.2.2, AS), the maternal toxicity NOAEL was 10 mg/kg bw/day based on decreased bodyweight gain and food consumption observed at **45 mg/kg bw/day**, and developmental toxicity NOAEL was set at 90 mg/kg bw/day based on the absence of effects reported. None of the effects observed were considered enough for STOT RE 2 classification.

In the immunotoxicity study in rats (B.6.8.2.1, AS), the administration of dodine in the diet at 0, 200, 500 and 1000 ppm (equivalent to 0, 18, 44, 83 mg/kg bw/day) for 28 days to females immunized with SRBC, did not produce adverse effects in survival, clinical signs, haematology, immunological examinations (anti-SRBC IgM titers), absolute and relative spleen and thymus weights and macroscopic examinations. However, decreases in bodyweight, bodyweight gain and food consumption were seen at 1000 ppm and based on these effects the NOAEL for general toxicity was set at 500 ppm (equivalent to 44 mg/kg bw/day). None of the effects reported were considered relevant for the decision on STOT RE classification.

#### **Studies in mice:**

In the 8-week oral (diet) study in mice (B.6.3.1.5, AS), mortality was reported in 1/5 female, one day after increasing the dose level from 100 to 1250 ppm. Decreases in the bodyweight of females and in the bodyweight gain of animals from both sexes were seen at 100/1250 ppm dose groups. The absolute spleen weight was reduced in the 100/1250 ppm female group. Moreover, all the males and most of the females at 100/1250 ppm had mild eosinophilia of the liver after treatment.

The **NOAEL** of this study has been set at 625 ppm (equivalent to **109.4 mg/kg bw/day**), based on the reduction of the bodyweight in females, the reduction in the bodyweight gain in both sexes, the decrease in the absolute weight of spleen in females and the increment of eosinophilia in the liver in both sexes, observed at the 100/1250 ppm dose group.

No effects from this study can be employed for STOT RE classification, as such effects were observed only at the 100/1250 ppm dose groups, in which two different doses were tested and therefore no clear dose-response relationships can be extracted.

In a 90-day oral dietary toxicity study in mice (B.6.3.2.4, AS), mortality was reported in females at 2500 ppm during the first 2 weeks of dodine treatment. Stiffening of the tail occurred also in females at 2500 ppm. A reduction in the bodyweight was seen in males at 2500 ppm and a reduction of bodyweight gain was observed in males from 1250 ppm and in females at 2500 ppm. Food consumption was reduced in both sexes from 1250 ppm. In males at 2500 ppm, increments in the percentage of neutrophils and in red blood cells width were observed. Also at 2500 ppm, increments were reported in blood urea nitrogen in both sexes, phosphorus levels in males and A/G ratio in females. An increment in the relative-to-body liver weight was observed in both sexes at 2500 ppm. The absolute spleen weights were reduced in both sexes from 1250 ppm and the relative-to-body spleen weight in females was decreased from 1250 ppm. An increase in the incidence of splenic lymphoid atrophy was observed in females at 2500 ppm (examination of spleen not extended to animals of lower dose groups). The incidences of lymphoid necrosis and atrophy in thymus were increased in females at 2500 ppm (examination not extended to animals of lower dose groups).

The **NOAEL** of this study was set at 600 ppm (**equivalent to 94 mg/kg bw/day**), based on the decreased bodyweight gain in males, the decrement in food consumption in both sexes and the decreases in the absolute and relative-to-body spleen weights in both sexes observed from 1250 ppm (equivalent to 181 and 223 mg/kg bw/day for males and females, respectively).

Significant effects in haematology in males at 2500 ppm (equivalent to 350 mg/kg bw/day) are out of the range for STOT RE 2 category (>10 mg/kg bw/day and ≤ 100 mg/kg bw/day).

Significant effects in clinical biochemistry in both sexes at 2500 ppm (equivalent to 350 and 305 mg/kg bw/day in males and females, respectively) are out of the range for STOT RE 2 category (>10 mg/kg bw/day and ≤ 100 mg/kg bw/day).

Effects in liver in both sexes at 2500 ppm (equivalent to 350 and 305 mg/kg bw/day in males and females,

respectively) are out of the range for STOT RE 2 category ( $>10$  mg/kg bw/day and  $\leq 100$  mg/kg bw/day). Effects in spleen in both sexes at 1250 ppm (equivalent to 181 and 116 mg/kg bw/day in males and females, respectively) are out of the range for STOT RE 2 category ( $>10$  mg/kg bw/day and  $\leq 100$  mg/kg bw/day). Effects in thymus in females at 2500 ppm (equivalent to 305 mg/kg bw/day) are out of the range for STOT RE 2 category ( $>10$  mg/kg bw/day and  $\leq 100$  mg/kg bw/day).

In a 78-week oral study in mice (B.6.5.2, AS), NOAEL for toxicity was considered to be 200 ppm (equivalent to 29.2 and 38.3 mg/kg bw/day for males and females, respectively), based on clinical signs in males, decreased bodyweight in both sexes and food consumption in both sexes at 750 ppm (equivalent to 109.8 and 136.2 mg/kg bw/day for males and females, respectively). Effects were clearly above the cut-off value for STOT RE 2 after a 78-week period ( $\leq 16.7$  mg/kg bw/day).

#### Studies in dogs:

In the 6-week oral range-finding toxicity study in Beagle dogs (B.6.3.1.6, AS), the administration of dodine in capsules caused toxicity in animals treated at 25 mg/kg bw/day for 6 weeks. Conclusions can hardly be extracted from lower doses, as they were only applied for short times. Adverse effects as increases of salivation, emesis, liquid faeces and bodyweight loss and decrease in food consumption were reported in treated dogs. The substance also seemed to have a direct impact in the amount of undigested food found in the stomach. No effects relevant for STOT RE were found in this study and a NOAEL was not derived due to the high complexity of doses and exposure times employed and the absence of negative controls.

In the 90-day oral toxicity study in Beagle dogs (B.6.3.2.5, AS), it was shown that the administration of dodine in capsules reduced the bodyweight in females and reduced the bodyweight gain in both sexes at 20 mg/kg bw/day. The food consumption was reduced in male and female dogs also at 20 mg/kg bw/day. The **NOAEL** of this study was set at **10 mg/kg bw/day**, based on decreased bodyweight in females and bodyweight gain in both sexes and the decrease in food consumption in both sexes observed at 20 mg/kg bw/day. In conclusion, there were no effects relevant for STOT RE in this study.

In the 52-week oral toxicity study in Beagle dogs (B.6.3.3.1, AS), the supplemental feeding to three dogs (a female at 10 mg/kg bw/day, a male at 20 mg/kg bw/day and a female at 20 mg/kg bw/day) was needed after the exhibition of notably marked bodyweight losses, starting during the first few weeks of dodine administration in capsules. White blood cells, segmented neutrophils and eosinophils counts were increased in females at 10 mg/kg bw/day. The **NOAEL** of this study was set at **2 mg/kg bw/day**, based on the supplemental feeding required in one female and increased WBC count, segmented neutrophils and eosinophils in females at 10 mg/kg bw/day. Significant effects in haematology in females at 10 mg/kg bw/day are out of the range for STOT RE 2 category ( $>2.5$  mg/kg bw/day and  $\leq 25$  mg/kg bw/day, applying Haber's rule).

In a 1-year oral dietary toxicity study in Beagle dogs (B.6.3.3.2, AS), dodine administration caused dose-response reductions in bodyweight gains, thyroid weight increments and increases in the incidence of findings in thyroid glands from 50 ppm. A **NOAEL** was not set for this study because of the absence of relevant information about the methodology and because most of the data were not shown. For these reasons also, none of the effects reported were considered relevant for the decision on STOT RE classification.

#### Studies in rabbits:

In a dose-range study for a developmental study in rabbits (B.6.6.2.3, AS), the maternal toxicity NOAEL was 70 mg/kg bw/day based on decreased bodyweight gain, decreased food consumption, the increased findings in necropsy (liquid contents in caecum and gaseous distension) and increased incidence in histopathological findings in stomach, kidney and liver observed at **100 mg/kg bw/day**. Five dams at 100 mg/kg bw/day and one dam at 70 mg/kg bw/day were humanely killed due to morbidity signs. At 100 mg/kg bw/day, there was an increase in the incidence of dams with liquid contents and gaseous distension in caecum and histoathological findings in stomach, liver and kidney. None of the effects observed were considered enough for STOT RE 2 classification.

In a developmental study in rabbits (B.6.6.2.4, AS), the maternal toxicity NOAEL was 40 mg/kg bw/day based on increased mortality and clinical signs and reduced food consumption at 80 mg/kg bw/day. At 80 mg/kg bw/day one dam ♀ died at GD15 after showing breathing difficulties, one dam was humanely killed at GD11 after showing same clinical signs and one dam was killed because of poor condition. The incidence of dark patches in lung lobes was increased in dams at 40 mg/kg bw/day. None of the effects observed were considered enough for STOT RE 2 classification.

Table 49: Extrapolation of equivalent effective dose for toxicity studies of greater or lesser duration than 90 days [if adequate, otherwise please delete]

| Study reference             | Effective dose (mg/kg/day)   | Length of exposure | Extrapolated effective dose when extrapolated to 90-day exposure   | Classification supported by the study |

<sup>1</sup> See section 3.9.2.8 of CLP Regulation: effects considered not to support classification for STOT RE.

### 2.6.3.1.2 Comparison with the CLP criteria regarding STOT RE (specific target organ toxicity-repeated exposure)

A substance is classified with STOT RE under CLP when it has produced or has been shown to have the potential to produce significant toxicity in humans or be harmful to human health following repeated exposure by the oral, dermal or inhalation routes. This can be on the basis of human data or evidence from studies in animals that cause such effects at or below given guidance values ( $\leq 10$  mg/kg bw/day or  $\leq 100$  mg/kg bw/day in a 90 day oral study in the rat). All significant health effects that can impair function, reversible or irreversible, immediate and/or delayed are included under this classification.

In the oral 90-day study in rats (■■■■, 1982), no clear evidence of relevant effects for STOT RE classification were reported. The main adverse effect found in this study was a decrease in the bodyweight gain in at 55.84 and 60.44 mg/kg bw/day, in males and females, respectively. This effect, although having toxicological importance, does not itself indicate "significant" toxicity.

As it can be observed in the table 49 above, several effects relevant for STOT RE classification were shown in toxicity studies of greater or lesser duration than 90 days. For most of these effects, a clear pattern across the dataset was not found, being an increase in mortality associated to dodine administration the only effect repeatedly found.

Mortality was reported in the 28-day gavage study in rats, where males died from 200 mg/kg bw/day and females from 75 mg/kg bw/day. These doses were between the threshold values established in Regulation (EC) No. 1272/2008 for classification of a substance as STOT RE 2 values for oral 28-day studies ( $>30$  mg/kg bw/day and  $\leq 300$  mg/kg bw/day). Mortality was also reported in rats in the dose range-finding developmental toxicity study, in which one of the dams at 100 mg/kg bw/day (the highest dose tested) was killed due to morbidity signs (piloerection, hunched posture, red/brown staining around face, fore-paws and mild ataxia) at gestation day 16. Extrapolating to the equivalent effective dose from a 11-day study to a 90-day study, a dose of 12 mg/kg bw/day was calculated, being this value between the threshold value of established in Regulation (EC) No. 1272/2008 for classification of a substance as STOT RE 2 for oral 90-day studies ( $>10$  mg/kg bw/day and  $\leq 100$  mg/kg bw/day). Mortality was not reported in the rest of studies performed in rats, but it should be highlighted that in none of this studies a dose equal or above 100 mg/kg bw/day was tested.

In dogs, no deaths were reported the 90-day or the 52-week studies performed. However, in the 52-week study it was stated that supplemental feeding was required to preclude mortality from 10 mg/kg bw/day. Extrapolating to the equivalent effective dose from a 52-week study to a 90-day study, a dose of 40 mg/kg bw/day was calculated, being this value between the threshold value established in Regulation (EC) No. 1272/2008 for classification of a substance as STOT RE 2 ( $>10$  mg/kg bw/day and  $\leq 100$  mg/kg bw/day).

In the two studies available in rabbits, mortality was reported. In the dose range-finding developmental toxicity study, 5 of 10 dams died at 100 mg/kg bw/day and 1 of 10 dams was humanely killed due to morbidity signs at 70 mg/kg bw/day. Extrapolating to the equivalent effective dose from a 13-day study to a 90-day study, a dose of 10 mg/kg bw/day was calculated, being this value  $\leq 10$  mg/kg bw/day as established in Regulation (EC) No. 1272/2008 for classification of a substance as STOT RE 1. In the developmental toxicity study in rabbits, three females died at 80 mg/kg bw/day (1 died, 2 were killed due to poor condition): one died at gestation day 15 after showing breathing difficulties, one humanely killed at gestation day 11 after showing same clinical signs and a third female was killed because of poor condition. At 40 mg/kg bw/day, one female was found dead, however it was due to accidental damage during dosing. Therefore, extrapolating to the equivalent effective dose from a 13-day study to a 90-day study, a dose of 12 mg/kg bw/day was calculated, being this value between the threshold value established in Regulation (EC) No. 1272/2008 for classification of a substance as STOT RE 2 ( $>10$  mg/kg bw/day and  $\leq 100$  mg/kg bw/day).

Taking all together, in the opinion of the RMS, dodine should be classified as STOT RE 2 due to mortality arising after repeated oral exposure to relatively low doses and observed in several species.

According to Regulation (EC) No. 1272/2008, an attempt should be made to determine the primary target organ of toxicity. However, the nature of the effect, together with the data available, has not allowed for further details.

### 2.6.3.1.3 Conclusion on classification and labelling for STOT RE (specific target organ toxicity-repeated exposure)

Dodine is proposed to be classified as **STOT RE 2: H373**: May cause damage to organs (undetermined) through prolonged or repeated oral exposure.

2.6.4 Summary of genotoxicity / germ cell mutagenicity [equivalent to section 10.8 of the CLH report template]

Table 50: Summary table of genotoxicity/germ cell mutagenicity tests *in vitro*

**2.6.4.1 Short summary and overall relevance of the provided information on genotoxicity / germ cell mutagenicity**

The potential genetic toxicity of dodine has been studied by a test battery that include tests to detect gene mutations (in bacterial and mammalian cells) and structural and numerical chromosome damage in both *in vitro* and *in vivo* tests (chromosomal aberrations test in mammalian cells and micronucleus tests in mice). No studies in germ cells were submitted.

Nine studies have been submitted, eight of them were previously evaluated in the DAR (2009). One new *in vitro* chromosomal aberration study and one re-evaluation of an *in vitro* gene mutation test have been submitted. All the studies were assessed according to the current guidelines.

Under the OECD TG 471 guideline, three studies were presented with negative results. All the strains required by the current guideline were covered by the reported studies. Exposure of *Salmonella typhimurium* and *Escherichia coli* tester strains to dodine did not produce an increased number of reversions, with and without metabolic activation at the tested doses.

Two mammalian gene mutation studies were submitted according to the OECD TG 476. Dodine did not induce mutations under the conditions of any of the tests. Dodine was considered non-mutagenic in the HGPRT-locus in CHO cells under the conditions of this *in vitro* test both with and without metabolic activation. MLA was re-evaluated according to current guideline, the study was considered to be in compliance with the OECD TG 490 guideline. Under the conditions used in the study, dodine was not mutagenic at the TK-locus of mouse lymphoma L5178Y cells both with and without metabolic activation.

Dodine did not induce chromosomal aberrations in cultured human lymphocytes, in any of two assays performed both with and without metabolic activation.

Dodine did not induce the formation of micronuclei in mouse polychromatic erythrocytes following doses of up to 500 mg/kg bw. In the first study no signs of toxicity were apparent, either indication on whether the bone marrow was reached. In the second study, signs of systemic toxicity were detected at the higher doses (200 and 400 mg/kg) indicating that the test chemical could be systemically available and, thus, also the bone marrow was reached. A complete assessment in relation to the evidence of bone marrow exposure in line with EFSA recommendation was provided (see summary in Vol. 3 B6), the weight of evidence of the evaluation of toxicity data shows that bone marrow exposure in the *in vivo* micronucleus studies can be considered.

Dodine has been tested for potential genotoxic properties (gene mutation, clastogenicity and aneugenicity) in a group of *in vitro* and *in vivo* assays. In any of them dodine showed evidence of *genotoxic potential*. Therefore, with the available dataset, dodine is not considered to be of genotoxic concern.

**2.6.4.2 Comparison with the CLP criteria regarding genotoxicity / germ cell mutagenicity**

No human data are available for dodine, therefore a classification as Muta. 1A is not supported. There are no data from *in vivo* heritable germ cell mutagenicity tests showing mutagenic effects in germ cells of humans therefore a classification as Muta. 1B is precluded. Dodine is negative in acceptable *in vitro* tests and *in vivo* somatic cell mutagenicity tests in mammals. Therefore, classification is not warranted for germ cell mutagenicity.

**2.6.4.3 Conclusion on classification and labelling for genotoxicity / germ cell mutagenicity**

Based on the data available for dodine and according to the criteria under Regulation (EC) No 1272/2008, **no classification of genotoxicity / germ cell mutagenicity** can be derived.

**2.6.5 Summary of long-term toxicity and carcinogenicity [equivalent to section 10.9 of the CLH report template]**

**2.6.5.1 Short summary and overall relevance of the provided information on long-term toxicity and carcinogenicity**

Three long-term toxicity and carcinogenicity studies (two conducted in rats and one in mice) have been provided to support the renewal of the active substance. Two of them were included in the original DAR (2009) in support of the inclusion of dodine in Annex I of Directive 91/414/EEC, and had been reassessed for the renewal purpose. These two studies were conducted according guidelines and presented minor deviations that did not compromise the acceptability of the study; therefore, they are deemed acceptable to assess de chronic toxicity and carcinogenicity potential of the active substance. Additionally, a new study conducted in rat has been provided, however, it showed important methodological and reporting deviations that compromise the acceptability.

-In the 106-week oncogenicity study in rats (B.6.5.1), dodine was tested at dose levels of 0, 200, 400 and 800 ppm (equivalent to 0, 10.17, 20.34 or 41.93 mg/kg bw/day for males and 0, 13.19, 26.5 or 53.50 mg/kg bw/day for females, respectively) for 106 weeks.

No important differences in mortality rates were observed between treated groups and controls for both sexes, only a slight decrease was observed in top dose male group after 2-year (38.3% vs 50% in controls).

Clinical signs related with potential neurotoxic effect on the nervous system were described. A statistically significant increase in the absence of grasping was found in top dose male group, compared with controls; whereas a significant trend was obtained for the absence of grasping, traction and righting reflexes incidences in dodine-male treated groups. On the other hand, a dose-related increase in the hunched posture incidence was revealed in males. Moreover, increased reduced motor activity and piloerection incidences were observed in males dodine-treated groups, compared with controls.

Slight statistically significant decreases in bodyweight were recorded in top dose male group throughout week 1-37 (5-8%) and weeks 85-89 (7-8%), whereas in females were noted throughout whole study (4-16%), compared with controls. On the other hand, slight reductions, not statistically significant, were recorded in female mid dose groups throughout study. Regarding bodyweight gains, a reduction was observed in most of the weeks throughout study in both sexes at high dose, whereas isolated reductions or increases, without dose relationship, were found in low and mid dose groups.

Food consumption was mostly decrease through sporadic weeks in top dose male (5-12%) and female (4-16%) dose groups without showing a clear dose relationship and consistency throughout the whole study.

Ophthalmoscopy examination was performed without showing treatment-related findings.

Regarding clinical chemistry parameters, a statistically significant lower mean alkaline phosphatase activity (18%) was seen at week 26 in top dose male group. However, this difference was mainly attributed to unusually high activities in two rats in the control group. On the other hand, at week 26, in females from high and low dose group, and at week 78 in males at mid dose, a tendency towards lower triglycerides concentrations was observed compared to controls. However, these changes were transient and no clear dose- relationship was noted. Moreover, at week 78, mean potassium concentration was higher (9%) in top dose female group, however, this difference was not considered biologically or toxicologically significant due to this parameter was not significantly altered in other weeks or dose groups. Additionally, mean alkaline phosphatase activities were higher at top and mid dose female groups (310% and 150% for top and mid dose groups, respectively) at week 104.

Urinalysis results showed a trend towards high protein content at week 25 in all male treated groups, and at week 25 and 51 in top dose female group compared with controls. Statistically significantly lower mean urinary volumes were noted at top dose male group at week 25 and 51 (47% and 29%, respectively), and in females at week 51 (46%). On the other hand, isolated statistically significant changes, without replicates at other measure time points, were recorded at week 25 in refractive index and pH in males of top dose group.

Haematology analysis revealed decreases on mean total white blood cell count (24%) in top dose male group at week 26. This variation was accompanied by a lower mean absolute lymphocyte count (26%). The same trend, but none statistically significant, was noted at week 52 in which mean total white blood cell count (22%) and mean absolute lymphocyte count (20%) were lower than controls. In females, statistically significantly higher mean prothrombin times were observed at week 26 at 800 ppm (5%) and at week 52 at low, mid and high dose groups (7%, 6% and 8% respectively). At week 104, mean corpuscular haemoglobin was statistically significantly higher (12%) at male mid dose group, compared with controls. This difference appeared to be attributable primarily to one rat, which had high mean corpuscular haemoglobin, because of a slightly lower red blood cell count and normal haemoglobin concentration; mean corpuscular volume was also higher for this animal.

Organ weight data at week 53 showed isolated statistically significant differences in different organs without a dose-relationship. On the other hand, organ weight data recorded at completion study (week 104), revealed a trend towards lower mean terminal bodyweight in top dose males (5%) and females (11%) dose groups, consistent with the lower bodyweight gain of these groups during the study. An increase, without a clear dose response, was noted in relative brain weight in females at mid and high dose (14% and 12%, respectively). On the other hand, increased absolute (11% and 6% for mid and high dose groups, respectively) and relative (11% and 12% for mid and high dose groups, respectively) epididymis weight were recorded compared with controls. A reduction, without a dose response and statistical significance, were noted in relative adrenal weight in males treated groups. An increase, without statistical significance, in the relative uterus weight was only observed in top dose female group. Additionally, a decreased trend, not statistically significant and not clear dose related, was observed in absolute and relative ovary weight in all females dodine treated groups, and in relative kidney weight in all males dodine treated groups, whereas in females, an increased trend was recorded for relative kidney weight.

Increases of enlarge (mid and top dose) and white mottling (top dose) incidences in adrenal gland were found in female-dodine treated groups, compared with controls. Moreover, increases of preputial gland abscess incidence was found in mid and top dose male groups compared with controls. On the other hand, increases small thymus occurrences (top dose), and decreases ovary cyst incidences (low, mid and high dose) were noted in female groups. No other relevant incidences were detected during necropsy examination in the female and male rats at any dose level.

Histopathology examination revealed increases in the incidences of ovary granulosa/theca cell hyperplasia, characterized by focal increase in number of granulosa/theca cells, in high dose female group (14.3% vs 5.8% in controls), showing statistically significance in prevalence tumour test. By contrast, reduction in pelvic mineralization in kidney (males) and bile duct hyperplasia in liver (females) incidences were noted in all dodine-treated groups. On the other hand, a slight not dose related increases incidences of prostate atrophy were recorded in all male dodine-treated groups.

Regarding neoplastic findings, increased benign ovary cystadenomas were noted in dodine treated-groups (0%, 9%, 14% and 6%, for control, low, mid and high dose groups, respectively). However, only one malignant cystadenocarcinomas were recorded in control and mid dose groups (1.5% and 1.7% for controls and mid dose

groups, respectively). Moreover, there was a reduction in the benign endometrial stromal polyp incidences in the uterus at top dose female group (9% vs 17% in controls). On the other hand, metastatic mammary gland adenocarcinoma in lung was detected in mid and high dose females groups, respectively. An increase, not dose related, of malignant adenocarcinomas incidences were noted in mammary gland of females from mid dose group (10, 14.5, 24.6 and 12.9% for control, low, mid and high dose groups). Remarkably, thyroid neoplasm observations were increased in males. First, non-statistically significant (prevalence tumour test), but dose related, increased incidences of combined thyroid adenomas and carcinomas were noted (35%, 40%, 45% and 53% for controls, low, mid and high dose group). The incidences in treated groups exceed the historical control range (27-38%). When incidences were analysed separately, thyroid C-cell adenoma occurrences were increased in treated groups, without a dose-response pattern and statistical significance (29%, 38%, 33% and 42% for controls, low, mid and high dose group) exceeding the HCD range for adenomas (25-32%) in all treated groups. On the other hand, thyroid C-cell carcinoma occurrences were increased in mid and top dose male group, without a dose-response pattern and statistical significance (6%, 2%, 12% and 11% for controls, low, mid and high dose group) exceeding the HCD range for carcinomas (4-10%) in mid and high dose groups.

Overall, **NOAEL for carcinogenicity** could not be established based on increased thyroid C-cell adenomas and carcinomas incidences in males observed at low dose (200 ppm, equivalent to 10.17/13.19 mg/kg bw/day for males/females). **NOAEL for toxicity** was considered to be **400 ppm** (equivalent to 20.34/26.5 mg/kg bw/day for males/females), based on clinical signs, decreased bodyweight and food consumption at high dose.

-In the 78-week oncogenicity study in mice (B.6.5.2), dodine was tested at dose levels of 0, 200, 750 and 1500 ppm (equivalent to 0, 29.2, 109.8 or 224.8 mg/kg bw/day for males and 0, 38.3, 136.2 or 275.2 mg/kg bw/day for females, respectively) for 78 weeks.

Mortality was dose-related decrease in male-dodine treated groups, compared with controls. There was a significant negative trend test in mortality ( $p < 0.01$  for both Cox-Tarone and Gehan-Breslow tests) associated with a significantly decreased mortality in the high-dose group compared with controls (3/70 vs. 16/70;  $p < 0.01$  for both tests). No differences were observed in female-dodine treated groups compared with controls.

Several clinical signs were described for both sexes. Increased incidence of whole body tremors was mainly noted in mid and high dose groups for males and females (~13-14% in males and 11-13% in females compared with controls). Malocclusion occurrences was considerably increased in high male dose group (18.6% vs 5.7% in controls), whereas a slight increase of irregular respiration (4.3% vs 0% in controls) and rough hair coat incidences (11.4% vs 0% in controls) were found in top dose female group. On the other hand, increased dose-related incidences of dilated pupil and excessive salivation were mainly observed in the three male-dodine treated groups and in mid-top male dose groups, respectively; whereas increases, not dose related of these incidences were recorded in female dodine-treated groups.

Statistically significantly lower bodyweights were recorded at top male (3-10%) and female (4-14%) dose groups throughout whole study, compared with controls. At mid dose groups, statistically significant reductions were mainly noted from week 30 to study termination for both sexes (2-5% for males and 4-10% for females, respectively), whereas at low dose groups, isolated reductions were recorded through few weeks for both sexes. Mean bodyweight gains of the top dose groups were significantly reduced for males and females through weeks 1-14 (26%), and for females through weeks 14-54 (36%) and 54-78 (63%), showing an overall mean bodyweight gain for males/females of 26/35%, respectively. At mid dose, overall mean bodyweight gain for females was significantly reduced compared controls (20%), whereas a slight reduction, not statistically significant, was found in males (5%). By contrast, slight increase (3%) and decrease (11%) was recorded in males and females from low dose groups, respectively.

Mean food consumption was generally reduced at top dose groups for both sexes throughout whole study (5-16% for males and 5-19% for females, respectively), compared with controls. On the other hand, at mid dose groups, statistically significant reductions were mainly noted at the first half of the study in males (5-8%), and practically through entire study in females (5-16%). In low dose groups, isolated and slight reductions were noted in males through study.

Regarding bodyweights at study termination, absolute (high dose: 12/11% for left/right) and relative (mid dose: 7/8% for left/right; and high dose: 31/30% for left/right) kidney weights were significantly increased in females. Moreover, relative liver and brain weights were statistically significant increased in top dose groups for both sexes (13/14% for males/females liver weight, and 8/11% for males/females brain weight). On the other hand, no dose-related changes, nor statistically significant results, were observed in another organ weights.

Necropsy examinations revealed slight increases of light focus area in the liver, and kidney cyst incidences in top dose male group, compared with controls. In spleen, large occurrences were reduced in mid and high dose groups for both sexes, whereas small spleen observations were slightly increased in top dose females, compared with controls. Regarding reproductive organs, small testes observations were increased in top dose male groups, whereas large uterus incidences were decreased in top dose female group. No other relevant incidences were detected during necropsy examination in male and female mice at any dose level.

Histopathology analysis did not show relevant adverse alterations in non-neoplastic findings. Most of the observations were reduced incidences noted between dodine-treated groups and controls. Firstly, in female livers, decreased incidences in haematopoiesis extra medullary (top dose), hypertrophy hepatocellular (mid and top dose), infiltrate lymphohistiocytic (mid and top dose) and neutrophilic (low, mid and top dose) were recorded. On the other hand, reductions in hepatocyte necropsy incidences were mainly noted in mid dose male group and in top dose groups for both sexes, compared with controls.

In kidney, decreases in infiltrate lymphohistiocytic incidences, as noted in liver, were also found in low, mid and top dose female group. On the other hand, cyst incidences were increased in dodine-treated males, but were decreased in dodine-treated females, compared with controls. Moreover, dilatation pelvis occurrences were reduced in dodine-treated males, whereas hyperplasia of tubular cell incidences were mainly increased in top dose male group. Amyloid decreases were noted in mid dose (female) and top dose (male and female) groups.

Moreover, an increased, not dose related, of inflammation occurrences in the prostate were recorded in low and top dose groups (6.7%, 14.3%, 0% and 16.7% for controls, low, mid and high dose groups, respectively), compared with controls.

On the other hand, neoplastic findings were mainly described in livers for both sexes. An increased incidences of hepatocellular adenomas were observed at high dose groups for both sexes (13%, 12%, 15% and 23% for controls, low, mid and high dose males groups; and 0%, 2%, 2% and 7% for controls, low, mid and high dose females groups, respectively), in which a statistically significant trend was displayed for females. All the recorded incidences in males groups (including controls) were higher than mean (6.3%) and out of the range (4.1-10%) of the accepted HCD; whereas in females only top dose group exceed both the mean (1.2%) and the range (0-3.3%) of HCD. On the other hand, no relevant increases were noted regarding hepatocellular carcinomas in dodine-treated groups (3.3%, 0, 5% and 1.7% for controls, low, mid and high dose males groups; and 0, 1.7%, 0, and 1.7% for controls, low, mid and high dose females groups, respectively). When the effects were combined, increased incidences were also observed in high dose groups (17%, 12%, 20% and 25% for controls, low, mid and high dose males groups; and 0%, 3%, 2% and 8% for controls, low, mid and high dose females groups, respectively), showing a significant trend test in females, and the only significant group comparison difference with controls was for combined adenomas and carcinomas in females given 1500 ppm dose. The combined incidences in all males groups (including controls) were higher than mean (10.2%) and out of the range of HCD, with the exception of low dose group (range: 8.3-12.2%). On the other hand, the combined incidences in female-treated groups were slightly higher than HCD mean (2.4%), except mid dose group, whereas top dose group was the only that exceed the range (2-3.3%). Furthermore, no relevant differences were noted in another organs regarding neoplasm incidences, compared with controls.

Overall, **NOAEL for carcinogenicity** is established in **1500 ppm** (equivalent to 224.8/275.2 mg/kg bw/day for males/females) based on no evidence of carcinogenicity at high dose. **NOAEL for toxicity** is considered to be **200 ppm** (equivalent to 29.2/38.3 mg/kg bw/day for males/females), based on clinical signs (both sexes), decreased bodyweight (both sexes) and food consumption (both sexes).

Therefore, based on the available data, the **overall carcinogenicity NOAEL** could not be established based on increased thyroid C-cell adenomas and carcinomas incidences observed at low dose (200 ppm, equivalent to 10.17/13.19 mg/kg bw/day for males/females) in rats (106-week study).

-A non-guideline chronic toxicity study was conducted in CFN rats (B.6.5.3). Dodine was administered *via* feed diet to 40 male and 40 female CFN rats *per* group at concentrations of 0, 50, 200 or 800 ppm (equivalent to 0, 2.5, 10 and 40 mg/kg bw/day) throughout 104 weeks. This study is a published report that presented important deviations that compromised the acceptability, so no further conclusions can be drawn. No relevant treatment effects were described after dodine administration. Only systemic toxicity effects in bodyweights and food consumption were described at top dose.

#### 2.6.5.2 Comparison with the CLP criteria regarding carcinogenicity

Comparison with criteria for Category 1A classification: In accordance with the criteria in the CLP regulation,

classification for carcinogenicity Category 1A is reserved for substances known to have carcinogenic potential in humans. In the absence of human data for carcinogenicity, category 1A is not triggered.

Comparison with criteria for Category 1B classification: In accordance with the criteria in the CLP regulation, classification for carcinogenicity Category 1B is reserved for substances that are presumed to be carcinogenic in humans, and is largely based on data from animal studies where there is sufficient evidence to demonstrate animal carcinogenicity (presumed human carcinogen). This classification is not considered appropriate based on the available data in rat and mice studies.

Comparison with criteria for Category 2 classification: In accordance with the criteria in the CLP regulation, classification for carcinogenicity Category 2 is reserved for substances where there is evidence obtained from human and/or animal studies but which is not sufficiently convincing to place the substance in Category 1. The available data suggests a carcinogenicity potential of dodine in rat, but no in mice.

### Rat

Thyroid C-cell adenomas: Benign C-cell adenomas were increase without showing a dose-response in all male-dodine groups (29%, 38.4%, 33.3% and 42% for controls, low, mid and high dose group). The results did no show statistically significance when dodine-treated groups were compared with controls nor a significant trend. The incidences of dodine-treated groups exceeded the HCD range for adenomas (25-32%), whereas the overall HCD mean (28.7%) was overcome in all groups, including controls.

On the other hand, the thryoid C-cell adenomas in females were increased in low dose group, but no at mid or top dose (29%, 35.8%, 29.8% and 24.6% for controls, low, mid and high dose groups). The results did no show statistically significance when dodine-treated groups were compared with controls nor a significant trend. Only the incidences of low dose group exceed the HCD range for adenomas (25-32%), whereas the overall HCD mean (28.7%) was overcome in all groups, except in the top dose female group.

Thyroid C-cell carcinomas: Malignant C-cell carcinomas were increase without showing a dose-response in mid and top male-dodine groups (6%, 2%, 11.7 and 11.3% for controls, low, mid and high dose groups). The results did no show statistically significance when dodine-treated groups were compared with controls nor a significant trend. The incidences of mid and high dodine-treated groups exceeded the HCD range (4-10%), and the overall mean (6.73%) for carcinomas.

On the other hand, the thryoid C-cell carcinomas in females were increased exclusively in low dose group, but no at mid or top dose (7.2%, 13.2%, 12.3% and 6.6% for controls, low, mid and high dose groups). The results did no show statistically significance when dodine-treated groups were compared with controls nor a significant trend. The incidences of female dodine-treated groups exceeded the HCD range (4-10%), and the overall mean (6.73%) for carcinomas.

Combined thyroid C-cell adenomas and carcinomas : Combined C-cell adenomas/carcinomas were increase in a dose related pattern in all male-dodine treated groups (35%, 40%, 45% and 53% for controls, low, mid and high dose groups). No statistical analysis were performed for the combined incidences. The incidences of all male-dodine treated groups exceeded the HCD range (27-38%), and the overall mean (32.74%) for the combined incidences.

On the other hand, combined C-cell adenomas/carcinomas in females were increased exclusively in low and mid dose groups, but no at top dose (36.2%, 49%, 42.1% and 31.1% for controls, low, mid and high dose groups). No statistical analysis were performed for the combined incidences. The incidences of female low and mid dose groups exceeded the HCD range (27-38%), and the overall mean (32.74%) for the combined incidences, but no at high dose.

Therefore, according to the criteria contained in Regulation (EC) No. 1272/2008, point 3.6.2.2.3 (b):

“Sufficient evidence of carcinogenicity: a causal relationship has been established between the agent and an increased incidence of malignant neoplasms or of an appropriate combination of benign and malignant neoplasms in (a) two or more species of animals or (b) two or more independent studies in one species carried out at different times or in different laboratories or under different protocols. An increased incidence of tumours in both sexes of a single species in a well-conducted study, ideally conducted under Good Laboratory Practices, can also provide sufficient evidence. A single study in one species and sex might be considered to provide sufficient evidence of carcinogenicity when malignant neoplasms occur to an unusual degree with regard to incidence, site, type of tumour or age at onset, or when there are strong findings of tumours at multiple sites”.

“Limited evidence of carcinogenicity: the data suggest a carcinogenic effect but are limited for making a definitive evaluation because, e.g. (a) the evidence of carcinogenicity is restricted to a single experiment; (b) there are unresolved questions regarding the adequacy of the design, conduct or interpretation of the studies; (c) the agent increases the incidence only of benign neoplasms or lesions of uncertain neoplastic potential; or (d) the evidence of carcinogenicity is restricted to studies that demonstrate only promoting activity in a narrow range of tissues or organs.”

Consequently, RMS deems that the relevance of thyroid neoplasms cannot not be excluded for human risk, based on the increased thyroid C-cell carcinomas and combined adenomas/carcinomas in male rats compared with controls, and the fact that the incidences exceed the range and mean of the HCD provided for the laboratory. Since thyroid C-cell tumours appeared only in rats and only in males, the RMS considers that according Regulation (EC) No. 1272/2008, these thyroid tumours triggers classification as carcinogenic in category 2.

**Mice**

**Hepatocellular adenomas:** Benign liver adenomas were increased without showing a clear dose-response only in top dose male group (13.3%, 11.7%, 15% and 23.3% for controls, low, mid and high dose males groups). The results did no show statistically significance when dodine-treated groups were compared with controls nor a significant trend. All the incidences recorded in males groups (including controls) were higher than mean (6.3%) and out of the range (4.1-10%) of the HCD provided.

On the other hand, the liver adenomas in females were also increased without showing a clear dose-response only in top dose female group (0%, 1.7%, 1.7% and 6.7% for controls, low, mid and high dose females groups, respectively). The results did no show statistically significance when dodine-treated groups were compared with controls, but showed a significant trend. In contrast to males, only top dose female group exceed both the mean (1.2%) and the range (0-3.3%) of HCD.

**Hepatocellular carcinomas:** malignant liver carcinomas were not increased after dodine administration in any sexe (3.3%, 0, 5% and 1.7% for controls, low, mid and high dose males groups; and 0, 1.7%, 0, and 1.7% for controls, low, mid and high dose females groups, respectively). Statistically significance was not obtained, and the values were all lower or close to mean and range of HCD.

**Combined hepatocellular adenomas/carcinomas:** Combined hepatocellular adenomas/carcinomas were slightly increased in mid and high male-dodine treated groups (16.7%, 11.7%, 20%, and 25% for controls, low, mid and high dose males groups). The results did no show statistically significance when dodine-treated groups were compared with controls nor a significant trend. The combined incidences in all males groups (including controls) were higher than mean (10.2%) and out of the range of HCD, with the exception of low dose group (range: 8.3-12.2%).

On the other hand, combined liver neoplasm incidences in females were slightly increased without showing a clear dose-response in all female-dodine treated groups, being the top dose group the group that showed the highest increase compared with controls (0%, 3.3%, 1.7% and 8.3% for controls, low, mid and high dose females groups, respectively). The results showed statistically significance only in top dose group compared with controls, and a significant trend. The combined female –treated groups incidences were slightly higher than HCD mean (2.4%), except mid dose group, whereas top dose group was the only that exceed the range (2-3.3%).

| <b>Multi-site responses</b>                 | No, malignant carcinomas–only appeared in thyroid.   |
| <b>Progression of lesions to malignancy</b> | Likely. Benign C-cell thyroid adenomas could develop in malignant neoplasm. More information is deemed necessary.  |
| <b>Reduced tumour latency</b>               | No, since the tumours were observed at study termination (106 week).   |

|  |  |
|--|--|
| <b>Whether response single or both sexes</b>                                   | Thyroid C-cell adenomas and carcinomas were mainly detected in male rats.  |
| <b>Whether responses are in a single species or several species;</b>           | Only malignant carcinomas (thyroid C-cell carcinomas) were observed in a single specie (rats).   |
| <b>Routes of exposure</b>  | Only experimental studies by oral (dietary) route are available.   |
| <b>Possibility of a confounding effect of excessive toxicity at test doses</b> | In rats, the increased incidences of combined thyroid C-cell adenomas and carcinomas were observed from low dose tested, in which no systemic toxicity was noted.<br>Hepatocellular mice adenomas were recorded only at high dose, whereas systemic toxicity was observed from mid dose. |
| <b>Mode of action and its relevance for humans</b>                             | Dodine mode of action studies were not provided. More experimental evidences are deemed necessary to suggest a plausible MoA.  |

**2.6.5.3 Conclusion on classification and labelling for carcinogenicity**

Based on the data available for dodine and according to the criteria under Regulation (EC) No. 1272/2008, RMS proposes the classification of this active substance as **carcinogenic in category 2 (H351)**.

**2.6.6 Summary of reproductive toxicity [equivalent to section 10.10 of the CLH report template]**

**2.6.6.1 Adverse effects on sexual function and fertility – generational studies [equivalent to section 10.10.1 of the CLH report template]**

Table 57: Summary table of animal studies on adverse effects on sexual function and fertility – generational studies

**2.6.6.1.1 Short summary and overall relevance of the provided information on adverse effects on sexual function and fertility – generational studies**

The potential effects of dodine on sexual function and fertility have been investigated in a two-generation reproductive toxicity study in Sprague Dawley rats. This study was performed according US EPA FIFRA 83-4 guideline, and it was therefore deficient in some endpoints such as number of implantations, corpora lutea and pre/post-implantation loss data were not reported, thyroid and pituitary weights were not measured, histopathology analysis was not performed in mid and low dose groups nor in pups, and HCD was not provided. However, this two-generation study is considered acceptable for the evaluation of sexual function and fertility assessment for the tested parameters.

In the two-generation reproductive study in rats, dodine was tested at 0, 200, 400 and 800 ppm dose levels (equivalent to 0, 13.4, 26.2, and 52.6 mg/kg bw/day for males and 0, 15.6, 31.2, 60.3 mg/kg bw/day for females, respectively), in which 30 pairs of males and females were mated from each test group. The rationale for dose selection was not described in the study.

Neither gross mortality or morbidity signs, nor treatment related clinical signs were observed in any dose group. Few sporadic animals were found dead or humanely killed. These deaths were not considered related to treatment.

In P adult animals, mean bodyweights from the 800-ppm group were consistently lower throughout the P generation (pre-mating, gestation, and lactation) after the initiation of treatment. Statistically significant differences were noted at high dose for the males throughout weeks 1-12 (6-9%); and for the females for weeks 3 (5%), 5-8 (5-6%), and 10 (5%) of pre-mating, throughout all gestation period (6-7%), and on lactation days 0 (6%), 4 (8%), 7 (7%), and 14 (8%) compared with controls. Mean bodyweights were also statistically significantly lower for females given 400 ppm on lactation day 4 (4%). No other significant differences were observed in the mean bodyweight at low and mid dose tested compared with controls. Mean cumulative bodyweight changes were statistically significantly lower in the high dose males (13-32%) and females (14-36%) groups throughout the whole pre-mating phase of P animals. On the other hand, bodyweight gain was statistically significantly higher in the high dose females group throughout lactation days 14-21 (20%) and throughout the whole lactation period (0-21 days; 84%) compared with controls. These differences in the trend were mainly caused due to dams from control, low and mid dose groups lost bodyweight during last week of lactation period.

In F1 adult animals, a statistically significant decrease in mean bodyweight was recorded at high dose male group (13-19%) during whole pre-mating phase compared with controls. On the other hand, a slight decrease, no statistically significant was recorded in mid dose male group. In females, a statistically significant decrease was noted in the high dose group during pre-mating (12-15%), gestation (12-14%) and lactation (8-15%) compared with controls. In the mid dose group, a reduction in bodyweight was also observed during the whole pre-mating, gestation and lactation phases, although was only statistically significant during the pre-mating week 0-8 (5-6%), gestation days 7 (5%), 14 (5%) and 20 (5%), and lactation days 4 (5%), 7 (4%) and 14 (5%). In the low dose female group, a slight decrease was noted in the whole pre-mating, gestation lactation phases, although only statistically significant results were obtained during the pre-mating week 2-3 (5%).

Absolute food consumption (g/animal/day) was statistically significant reduced in the high dose P male group from week 0 to 3 (7-14%) and in mid dose group in the first week (5%). There were no other significant differences in food consumption at high dose P male group at subsequent intervals or for males in the remaining test material-treated groups during the P generation, indicating that early decreases in food consumption were probably associated with decreased palatability. On the other hand, in the P female dose groups, mean food consumption was statistically

significant reduced throughout weeks 0-5 (6-15%) of pre-mating phase, and during lactation days 4-7 (10%), 7-10 (19%), and 10-14 (15%) in the 800 ppm dose group, whereas in the mid dose group, mean food consumption was statistically significantly lower during lactation days 7-10 (9%).

Mean food consumption was significantly lower in the high dose male groups throughout the F1 generation compared with controls (6-14%). No relevant differences were noted in the low or mid male dose groups. In F1 females, statistically significant reduction in food consumption was recorded at high dose group throughout pre-mating (9-18%), gestation (12-17%), and lactation (12-20%; except for days 0-4 of lactation) phases. Sporadic significant differences in mean food consumption were noted through week 4-5 (8%) at low dose group, and through weeks 3-4 (9%) and lactation days 7-10 (8%) at mid dose group.

Regarding macroscopic examinations, isolated statistically significant decreases were recorded in absolute left kidney (5%), thymus (17%), and brain (3%) weights at high dose male group of P generation, compared with controls. No statistically significant differences were noted in other P male organs from dodine-treated groups. On the other hand, P high dose females displayed increased relative adrenal weight (left and right), compared with controls (14%). Moreover, decrease in both absolute kidney weight (6%) were recorded in mid (only left kidney) and high dose P female groups, whereas relative brain weight was statistically significantly higher in high dose female group (7%).

In F1 males, statistically significant increases of relative weights were recorded at top dose level in right and left epididymis (13%), left (12%) and right testis (14%), left adrenal (21%) and brain (13%), compared with controls. On the other hand, absolute decreased weights were recorded in left (15%) and right kidney (14%), together with liver (16%) at high dose group. In the other dose groups from F1 male generation, only mid dose groups exhibited statistically significant decrease in left kidney absolute weight (7%) compared with controls. In F1 females, statistically significant increases in relative weights were recorded at top dose level in left (23%) and right adrenal (20%), brain (9%) and left ovary (11%); and in left adrenal (12%) at mid dose, compared with controls. On the other hand, absolute decreases weights were recorded in both kidneys in mid and high dose groups (5% and 11% for left kidney in mid and high dose groups, respectively; and 6% and 12% for right kidney at mid and high dose groups, respectively), together with liver (12%) and brain (4%) at high dose group.

In addition, no relevant differences were observed in necropsy analysis between P/F1 treated animals and controls. A slight increase, no statistically significant and no dose related, of lumen filled with fluid and red focus area incidences in the thymus were observed in P and F1 generation, whereas large pelvis in kidney and mottled thymus incidences were only observed in some F1 treated groups. The relevance of this findings is doubtful.

Histopathology examinations were only carried out in high dose groups and controls; in reproductive organs of females in the low and mid dose groups that failed to mate or that mated but failed to deliver a litter, and males that failed to sire progeny. Therefore, no adverse findings were recorded in P/F1 treated animals compared with controls.

Concerning estrous cycle in females and sperm parameters in males, no treatment-related differences were noted between dodine treated groups and controls in P and F1 adult animals.

Reproduction parameters such as mating, sex ratio or gestation length were not affected by treatment. Fertility indices (no. of females pregnant/no. females with positive signs of mating) for control, 200 ppm, 400 ppm and 800 ppm dose groups in the F1 generation were 100%, 93%, 90% and 90%, and 100%, 97%, 93% and 100% in the F2 generation. Therefore, the fact that trend observed during P-F1 generation was not further confirmed in the next generation, along with there was no statistical significance neither dose-response, the effect in fertility index observed in the P-F1 generation was deemed incidental and was ruled out as potential effect in sexual function and fertility. On the other hand, live birth index was statistically significant increase in the low and mid dose groups from F1 generation (96%, 98%, 100% and 97% for control, 200 ppm, 400 ppm and 800 ppm dose groups, respectively). Moreover, a decrease, not statistically significant and no dose-related, was noted in both F1 and F2 generations at mid and high dose groups in the mean total number of pups delivered per litter (8% and 3% for mid and high dose groups, respectively during F1 generation; and 11% and 7% for mid and high dose groups, respectively during F2 generation), and in the live pups/litter with live pups (5% and 1% for mid and high dose groups, respectively during F1 generation; and 11% and 7% for mid and high dose groups, respectively during F2 generation).

In the F1 pups, mean bodyweights were significantly lower for male and female pups from lactation days 4-21 in the high dose group; and on days 4 (pre-cull and post-cull, females only), 14 (females only), and 21 (males and females) for mid dose pups group. Regarding organ weights in this generation, absolute kidney (both) and liver weights were statistically significantly lower in high dose male group (16% and 18%, respectively), whereas relative brain weight was increased (12%), compared with controls. No statistically significant differences were noted in

other F1 male pups from treated-groups regarding organs weights. On the other hand, in F1 females weanling pups, statistically significant differences were only observed in absolute and relative spleen weight at mid dose level (25% and 17%, respectively).

In F2 pups, mean bodyweights were statistically significantly lower on days 4 (pre-cull and post-cull, males only), 7, 14, and 21 for pups in the 800 ppm dose group, and on days 14 (males only) and 21 for pups in the 400 ppm dose group. Regarding organ weights, absolute kidney (both), spleen and liver weights were statistically significantly lower in high dose male group (16%, 28% and 17% for kidneys, spleen and liver, respectively), whereas relative brain weight was increased (18%), compared with controls. No statistically significant differences were noted in other F2 male pups from treated-groups regarding organs weights, except absolute left kidney weight in mid dose group. On the other hand, in F2 females weanling pups, absolute kidney (both), thymus, spleen and liver weights were statistically significantly lower in high dose group (14/17% for left/right kidney, 28% for thymus, 22% for spleen and 17% for liver, respectively), whereas relative brain weight was increased (15%), compared with controls. No statistically significant differences were noted in other organs at 800-ppm or low dose groups in F2 female pups.

Furthermore, no treatment related findings were recorded in any of F1 and F2 examined pups during necropsy evaluation.

Overall, there were no effects on sexual function and fertility at doses tested, although effects on developmental and parental were seen at mid and high dose tested.

Therefore, a **NOAEL for sexual function and fertility** has been established at **800 ppm (52.6/60.3 mg/kg bw/day for males/ females)** based on no effects observed at high dose level.

**NOAEL for developmental toxicity** has been established at **200 ppm (13.14/15.6 mg/kg bw/day for males/ females)** based on decreased male and females pup weights in F1 and F2 generation.

**NOAEL for parental toxicity** has been established at **200 ppm (13.14/15.6 mg/kg bw/day for males/ females)** based on decreased bodyweights in F1 adult animals, and increased relative adrenal weight in F1 adult animals.

-Information regarding sexual function and fertility parameters were also provided in an acute and chronic toxicity study in CFN rat strain (B.6.6.1.2). This study was not GLP, no guideline was followed, and presented important methodological deficiencies. Animals were tested with 0 and 800 ppm (equivalent to 72 mg/kg bw/day). The various indexes calculated for the test and control animals, respectively, do not indicate any effect of feeding of 800 ppm of dodine on reproduction and lactation. The only difference of any apparent significance is a smaller mean litter size for the animals receiving dodine: 8.6 live pups per litter vs 11.6 live pups per litter for the controls. However, the authors of this publication stated that the litter size decrease in treated rats resulted from the prevalence of an unusually large litter size among the controls, rather than any diminution in fertility of the test animals. This conclusion could not be verified by the RMS, as no HCD was available for this laboratory, and no other reproductive studies were provided in the dossier with the CFN rat strain.

#### 2.6.6.1.2 Comparison with the CLP criteria regarding adverse effects on sexual function and fertility

No human information is available on the effects of dodine on the reproductive system. Information from a reliable two-generation study in rats showed that dodine has no effects on sexual function and fertility. The available study did not include the no. of implantations, corpora lutea and pre/post-implantation losses. However, data from this study is regarded conclusive for classification since sexual function and fertility parameters available such as mating, and fertility indices, sex ratio, and gestation length were not affected by treatment. No significant nor dose related effects were seen on litters in both studies and consequently potential impairment of fertility in relation with implantation is not considered.

Consequently, classification for sexual function and fertility is not warranted.

2.6.6.2 Adverse effects on development [equivalent to section 10.10.4 of the CLH report template]

**2.6.6.2.1 Short summary and overall relevance of the provided information on adverse effects on development**

Two main developmental toxicity studies, one conducted in rats (B.6.6.2.2), and one in rabbits (B.6.6.2.4), have been presented to support the renewal assessment of the active substance dodine. Both studies were preceded by their respective pilot studies (B.6.6.2.1 in rats, and B.6.6.2.3 in rabbits), performed to estimate the suitable dose levels for the main teratogenicity studies. Additionally, the main teratogenicity studies did not present a complete statistical analysis, therefore, ██████████ (2019), carried out a further re-analysis of the data described in each developmental toxicity study, so this information has been included in the respective studies in order of the

comprehensive assessment.

The preliminary study in rats (B.6.6.2.1) was designed to select the appropriate dose levels for the main teratogenicity study (B.6.6.2.2). In this pilot study, dodine was tested at dose levels of 0, 50, 70 and 100 mg/kg bw/day, in which 10 copulated females were assigned to each test group.

Only one female at high dose group was humanely killed due to morbidity signs (piloerection, hunched posture, red/brown staining around face, fore-paws and mild ataxia). Another female from same group showed wheezing. No other mortalities or clinical signs were recorded in dodine-treated groups.

Female bodyweights were decreased in a statistically significant manner in the mid and high dose dams at gestation day 13 (10% and 8%, respectively), although not statistically significant decreases were recorded throughout gestation day 6-16 in both groups (8-10% and 1-8% for mid and high dose groups, respectively), compared with control group. Besides, reduced bodyweight gain was statistically significant reduced at gestation day 6-13 in 70 and 100 mg/kg bw/day groups (26% and 48% for 70 and 100 mg/kg bw/day dose groups, respectively), although not statistically significant decreases were recorded throughout gestation day 6-16 in both groups (6-26% and 17-65% for mid and high dose groups, respectively), compared with control group.

Moreover, mean food consumption was also decreased throughout whole gestation period in all the dodine treated groups (7%, 15% and 24% for low, mid and high dose groups, respectively).

Necropsy dam evaluation revealed a slight increase in the kidney incidences (pelvic dilatation and enlarged; 30%) and ureters (dilatation; 20%) in the top dose group, compared with controls (0%). Moreover, one dam from high dose group exhibited alterations consistent with a long standing partial obstruction in the lower urinary tract (epithelial hyperplasia and chronic inflammation of the urinary bladder; ureters inflammation; pelvic dilatation and inflammation, together with nephritis in the kidney; and hyperplasia of the lumbar lymph node). These findings could have been caused by a small calculus in the bladder or urethra, which might have been voided some time before death.

Regarding sexual function and fertility parameters, fertility index was reduced in the top dose group (90%), compared with other dose and control groups (100%). Developmental checked parameters did not display relevant differences compared with controls. An increase, not dose related, in mean deaths and early resorptions were recorded in low and high dose groups. Besides, foetal bodyweight was slightly reduced (4%) compared with controls in the high dose group.

Therefore, a **NOAEL for developmental toxicity** has been established at **100 mg/kg bw/day** based on no effects observed at high dose level.

**NOAEL for maternal toxicity** has been established at **50 mg/kg bw/day** based on decreased bodyweight gain and food consumption.

The main study in rats (B.6.6.2.2), dodine was tested *via* oral gavage at dose levels of 0, 10, 45 and 90 mg/kg bw/day throughout gestation day 6 to gestation day 16, in which 25 copulated females were assigned to each test group.

No mortalities were observed during study in any of the tested groups. Isolated clinical signs were recorded in some treated dams. Three dams at high dose group showed excessive salivation after dosing for one or 2 days during the treatment period. On the other hand, there was another three animals with red/brown stained fur around the mouth at 90 mg/kg bw/day dose groups and one in the 45 mg/kg bw/day dose group. Besides, one dam from high dose group showed noisy breathing after dosing.

Statistically significant decreases in bodyweights were recorded in gestation day 9 (9%), 13 (8%) and 17 (8%), and in bodyweight gain throughout gestation day 6-9 (107%) and 6-17 (20%) at high dose group, compared with controls. No differences were observed in low and mid dose group.

Food consumption was statistically significantly lower than controls from gestation day 6-16 (13-37%) at high dose group; and on gestation day 6 (11%) and gestation day 8-10 (12-18%) at mid dose group.

On the other hand, only two dams from high dose groups showed necropsy observations (8% showed dark red areas on lung lobes). These effects were further confirmed in the histopathology analysis (8% congestion and 4% in haemorrhage into alveoli).

Regarding reproductive data, a slight increase in fertility index were observed in dodine treated groups compared

with controls (88%, 84%, 92% and 96% for controls, low, mid and high dose groups, respectively). Gestation length and mating index were not measured.

Developmental endpoints such as corpora lutea, implantations, resorptions (early and late), foetal weight and sex ratio did not show differences between dodine-treated groups and controls. A slight increase, not dose-related, in the mean uterus weight was found in mid and high dose groups (5% and 7% for mid and high dose groups, respectively), compared with controls

On the other hand, the visceral or skeletal findings recorded in foetuses were deemed variations that did not suggest adverse developmental effects.

Therefore, a **NOAEL for developmental toxicity** has been established at **90 mg/kg bw/day** based on no effects observed at high dose tested.

**NOAEL for maternal toxicity** has been established at **10 mg/kg bw/day** based on decreased bodyweight gain (6-9 GD) and food consumption.

The preliminary study in rabbits (B.6.6.2.3) was designed to select the appropriate dose levels for the main teratogenicity study (B.6.6.2.4). In this pilot study, dodine was tested at dose levels of 0, 70 and 100 mg/kg bw/day, in which 10 copulated females were assigned to each test group.

Five animals at high dose group and one in low dose group were humanely killed due to morbidity signs. These animals showed few faeces previous dead. Some animals also showed eye affectations and breathing difficulties.

Bodyweight data did not revealed differences between treated groups and controls. Food consumption was reduced at top dose group throughout GD 6-18 (31-71%), compared with controls, exhibiting a mean of 51% lower than controls.

Necropsy examinations indicated that the half of animals showed liquid contents and gaseous distension in caecum (50%) at high dose group, whereas at low dose group, only one animal (10%) showed this finding, compared with controls.

Most findings of histopathology analysis revealed effects on stomach, in which 50% of animals at high dose group showed colour or dark foci areas, in some cases with epithelium hyperplasia. Additionally, 20% of rabbits from top dose group showed chronic liver or kidney inflammation. On the other hand, no relevant findings were noted at low dose group.

Sexual function and fertility parameters were not affected in treated groups compared with controls. At 100 mg/kg bw/day group there was an increase in the pre-implantation loss (22% vs 14% in controls) and in the mean live implants that cannot be attributed to test treatment. The only concerning effect was the increase in the number of late resorptions seen at the highest dose level compared to controls (5 vs 0), regarded adverse taking into account the magnitude of the variation and the absence of a statistical analysis in this study.

Therefore, a **NOAEL for developmental toxicity** has been established at **70 mg/kg bw/day** based on the increase in the number of late resorptions at the highest dose level.

**NOAEL for maternal toxicity** has been established at **70 mg/kg bw/day** based on decreased bodyweight gain and food consumption, necropsy and histopathological findings in stomach, kidney and liver.

The main study in rabbits (B.6.6.2.4), dodine was tested *via* oral gavage at dose levels of 0, 10, 40 and 80 mg/kg bw/day throughout gestation day 6 to gestation day 16, in which 16 or 20 copulated females were assigned to each test group.

Four total mortalities were recorded throughout whole study: three occurred at high dose group (one animal dies at GD 15 after showing breathing difficulties, one animal was humanely killed at GD 11 after showing same clinical signs, and another was also killed because of poor condition), and one at mid dose group (accidental damage during dosing). Most of clinical signs were observed in 80 mg/kg bw/day dose group. 15% of rabbits showed liquid faeces, breathing difficulties and emaciation. Besides, 10% showed pale eyes and two dams (10%) suffered abortions. Another clinical signs with low incidences were recorded in this group. Blood in cage and breathing difficulties were noted in the mid and high dose groups, whereas liquid faeces were seen in all groups. On the other hand, in control and low dose groups, an abortion in each group was also recorded.

No differences were observed in bodyweights and bodyweights gain between treated groups and controls. Regarding food consumption, statistically significant reduction was recorded at high dose group in gestation days 6 (25%), 7 and 8 (30%) compared with controls. Moreover, in this group, sporadic reduction, without statistical significance, were noted during mid to late treatment period.

Necropsy examinations revealed isolated and low incidence findings in liver, kidney, intestine, stomach and uterus of treated dams. Remarkably, the incidence of dark patches in lung lobes was increased in mid (12.5%) and high dose (20%) groups compared with controls, in which the half of these animals presented breathing difficulties as clinical signs.

Fertility index was slightly reduced in high dose group compared with controls, in which three dams were not pregnant (94%, 94%, 100% and 85% for controls, low, mid and high dose groups, respectively). Gestation length and mating index was not measured.

Developmental parameters indicated variations after dodine treatment from 40 mg/kg bw/d without statistical significance and not clear dose-relationship. However, the clear maternal toxicity seen at the highest tested dose level of 80 mg/kg bw/d with mortality (1 dead and 2 killed dams), clinical signs, decrease in food consumption, dark patches in the lung compromises the interpretation of the relevance of co-occurring developmental effects for classification (for instance, the abortions, the number of post implantation losses and late resorptions). These increases in abortions, post implantation losses and late resorptions can be considered a direct consequence of maternal toxicity at 80 mg/kg bw/d but not at 40 mg/kg bw/d in which only dark patches in the lung were seen.

The visceral or skeletal findings recorded in foetuses did not show dose-relationship and were deemed variations that did not suggest adverse developmental effects.

Therefore, the **NOAEL for developmental toxicity** has been established at **10 mg/kg bw/day** based on developmental effects such as increase of post implantation losses and late resorptions seen from 40 mg/kg bw/day.

**NOAEL for maternal toxicity** has been established at **40 mg/kg bw/day** based on mortality, clinical signs and reduced food consumption noted at high dose tested.

#### Developmental effects observed in other studies

In the two-generation reproductive study in rats, dodine was tested at 0, 200, 400 and 800 ppm dose levels (equivalent to 0, 13.4, 26.2, and 52.6 mg/kg bw/day for males and 0, 15.6, 31.2, 60.3 mg/kg bw/day for females, respectively), in which 30 pairs of males and females were mated from each test group.

In the F1 pups, mean bodyweights were significantly lower for male and female pups from lactation days 4-21 at 800 ppm and for 400 ppm dose pups group on days 4 (precull and postcull, females only), 14 (females only), and 21 (males and females). Regarding organ weights in this generation, absolute kidney (both right and left) and liver weights were statistically significantly lower in high dose male group (16% and 18%, respectively), whereas relative brain weight was increased (12%), compared with controls. The effects at 800 ppm were seen in presence of maternal toxicity (decreases in bodyweight, bodyweight gain, food consumption and significant organ weight variations) and the slight decreases in pup weights at 400 ppm with slight maternal toxicity (slight reductions in bodyweight and food consumption).

In F2 pups, mean bodyweights were statistically significantly lower on days 4 (pre-cull and post-cull, males only), 7, 14, and 21 for pups in the 800 ppm dose group, and on days 14 (males only) and 21 for pups in the 400 ppm dose group. Regarding organ weights, absolute kidney (both), spleen and liver weights were statistically significantly lower in high dose male group (16%, 28% and 17% for kidneys, spleen and liver, respectively), whereas relative brain weight was increased (18%), compared with controls. No statistically significant differences were noted in other F2 male pups from treated-groups regarding organs weights, except absolute left kidney weight in mid dose group. On the other hand, in F2 females weanling pups, absolute kidney (both), thymus, spleen and liver weights were statistically significantly lower in high dose group (14/17% for left/right kidney, 28% for thymus, 22% for spleen and 17% for liver, respectively), whereas relative brain weight was increased (15%), compared with controls. No statistically significant differences were noted in other organs at 800-ppm or low dose groups in F2 female pups. The effects at 800 ppm were seen in presence of maternal toxicity (decreases in bodyweight, bodyweight gain, food consumption and organ weight variations and the slight decreases in pup weights at 400 ppm with slight maternal toxicity (slight reductions in bodyweight and food consumption and increase in the relative weight of the adrenals).

Furthermore, no treatment related findings were recorded in any of F1 and F2 examined pups during necropsy evaluation.

NOAEL for developmental toxicity has been established at 200 ppm (13.14/15.6 mg/kg bw/day for males/females) based on decreased male and females pup weights in F1 and F2 generation.

**2.6.6.2.2 Comparison with the CLP criteria regarding adverse effects on development**

No human information is available on the effects of dodine on development, but there is information from two reliable developmental studies conducted in rat and rabbit.

Developmental effects in rats

There were no adverse developmental effects in the rat teratogenicity studies.

In the multigeneration study in rats the significant decreases in pup weights at 400 ppm in F1 and F2 were of low magnitude (5-8%) and were seen in presence of slight maternal toxicity based on decreased bodyweights and increased relative adrenal weight in F1 adult females. Even if treatment-related, the effect is not sufficiently relevant for classification.

Developmental effects in rabbits

In the range-finding developmental study in rabbits the increase in the number of late resorptions seen at the highest dose level of 100 mg/kg bw/day compared to controls (5 vs 0) is considered of doubtful toxicological relevance taking into account the presence of maternal toxicity.

In the main developmental study in rabbits, a clear maternal toxicity was observed at high dose. Three mortalities (15%) apparently related to test substance administration were recorded at top dose group. No other deaths attributed to dodine- were recorded among groups. Moreover, several clinical signs were noted at this dose, whereas at mid and low dose groups, sporadic and low clinical signs incidences were observed.

On the other hand, the non-significant increase in post-implantation losses and late resorptions from 40 mg/kg bw/day were seen in presence of maternal toxicity at 80 mg/kw bw/day and without clear maternal toxicity at 40 mg/kg bw/day. In any case, effects at this intermediate dose level are not regarded sufficient for classification.

**Table 2.6.6.2.2/2: Main effects in rabbits potentially relevant for CLP**

| Study   | Dose level              | Developmental effects           | Maternal toxicity   |

In section 3.7.1.4 of Annex I to CLP Regulation it is stated that “*Developmental toxicity includes, in its widest sense, any effect which interferes with normal development of the conceptus, either before or after birth, and resulting from exposure of either parent prior to conception, or exposure of the developing offspring during prenatal development, or postnatally, to the time of sexual maturation. However, it is considered that classification under the heading of developmental toxicity is primarily intended to provide a hazard warning for pregnant women, and for men and women of reproductive capacity. Therefore, for pragmatic purposes of classification, developmental toxicity essentially means adverse effects induced during pregnancy, or as a result of parental exposure. These effects can be manifested at any point in the life span of the organism. The major manifestations of developmental toxicity include (1) death of the developing organism, (2) structural abnormality, (3) altered growth, and (4) functional deficiency*”.

According to the guidance on the application of the CLP criteria and based on the development effects observed in rats and rabbits, RMS proposes no classification for dodine as reproductive toxicant.

**2.6.6.3.1 Short summary and overall relevance of the provided information on effects on or via lactation**

The available information on the potential of dodine to cause adverse effects on the offspring via lactation or on lactation is contained in the generation reproductive study ( [redacted] [redacted] 1996; B.6.6.1.1).

In the generational study there is no clear evidence of adverse effects in the offspring due to transfer of test substance in the milk, or of adverse effect on the quality of the milk. Only decreased offspring bodyweights were observed on lactation period, but these were considered a direct effect of the solid diet or were related to maternal toxicity.

**2.6.6.3.2 Comparison with the CLP criteria regarding effects on or via lactation**

No human information is available on the effects of dodine on or via lactation, but there is information reliable from a two-generation reproduction studies in rats. Based on the data available, there were no effects to warrant classification of dodine for effects on or *via* lactation.

**2.6.6.4 Conclusion on classification and labelling for reproductive toxicity**

Based on the reproductive data available for dodine, and according to the criteria under Regulation (EC) No. 1272/2008, RMS proposes no classification for dodine.

**2.6.7 Summary of neurotoxicity**

Neurotoxicity studies with dodine were not available in the submitted dossier.

According to Commission regulation (EU) No 283/2013, neurotoxicity studies in rodents shall be performed for active substances with structures that are similar or related to those capable of inducing neurotoxicity, and for active substances, which induce specific indications of potential neurotoxicity, neurological signs or neuropathological lesions in toxicity studies at dose levels not associated with marked general toxicity. Performance of such studies shall also be considered for substances with a neurotoxic mode of pesticidal action.

Moreover, delayed polyneuropathy studies shall be performed for active substances of similar or related structures to those capable of inducing delayed polyneuropathy such as organophosphorus compounds.

Table 66: Summary table of animal studies on neurotoxicity

| Method, guideline, deviations if any, species, strain, sex, no/group | Test substance, dose levels duration of exposure | Results:<br>- NOAEL/LOAEL<br>- target tissue/organ<br>-critical effect at LOAEL | Reference |
|--|--|---|-----------|
| No animal studies on neurotoxicity are available                     |  |   |           |

Therefore, a review of the existing data has been carried out.

**Neurotoxicity findings in acute toxicity studies**

In an acute oral study in rats (██████████ 1999), hypoactivity was observed in all animals at 761 and 1285 mg/kg bw and impaired muscle coordination was seen in 2/5 males and 3/5 females at 1285 mg/kg bw. LD<sub>50</sub> values of 830 and 817 mg/kg bw were set for males and females respectively.

In an acute oral study in female mice (██████████, 2008), animals dosed at 1290, 1750 and 2300 mg/kg bw displayed a decreased spontaneous activity, showing reversibility in those animals which survived until the end of the study (one at 1290 and one at 1750 mg/kg bw) and in two females at 1750 and 2300, respectively. One animal at each dose of 1290, 1750 and 2300 mg/kg bw showed also decreased Preyer’s reflex and righting reflex. LD<sub>50</sub> value of female mice was set at 1354 mg/kg bw.

**Neurotoxicity findings in short-term studies**

In the 28-day oral gavage study in rats, salivation was increased in males and females from 75 mg/kg bw/day (██████████ 1994a). No other potentially neurotoxic findings were observed in the short-term data package.

**Neurotoxicity findings in genotoxicity studies**

In an *in vivo* mammalian micronucleus test (██████████ 1992), all remaining mice prior to euthanasia at the completion of the dose range finding study appeared languid in the groups in which 387.5 and 500 mg of dodine/kg bw were administered by gavage. No similar effects were reported during the main micronucleus assay in which doses up to 400 mg/kg bw were administered.

**Neurotoxicity findings in developmental toxicity studies**

In a dose-range finding developmental toxicity study in rats (██████████ and ██████████, 1989a), one dam treated at 100 mg of dodine/kg bw/day showed wheezing on GD 9 and another showed piloerection, hunched posture, red/brown stain around face and fore-paws and mild ataxia on GD 15 and 16.

In the main developmental toxicity study in rats (██████████ and ██████████, 1989b), 3 dams showed excessive salivation (after dosing for 1 or 2 days), 2 showed red/brown stained fur around the mouth (at 45 and 90 mg/kg bw/day) and 1 showed noisy breathing at 90 mg /kg bw/day.

In a dose-range finding developmental toxicity study in rabbits (██, 1989a), at 100 mg/kg bw/day, 1 animal was found dead at GD 13 with red staining around lower abdomen and another showed breathing difficult and noisy, and was slightly cyanosed and subdued.

In the main developmental toxicity study in rabbits ([REDACTED], 1989b), some dams showed breathing difficulties from 40 mg/kg bw/day and emaciation at 80 mg/kg bw/day.

**Neurotoxicity findings in long-term studies**

In the oral 106-week study in rats ([REDACTED] 1998), a significant increase in the absence of grasping was found in males at 800 ppm, whereas there were significant trend tests for the absence of grasping, traction and righting reflexes incidences in dodine-male treated groups. On the other hand, a non-significant but dose-related increase in hunched posture incidence was revealed in males. Moreover, increased reduced motor activity and piloerection incidences were observed in males dodine-treated groups compared with controls, although they were neither significant nor dose-response.

In the oral 78-week study in mice ([REDACTED] 1998a) increased incidence of whole body tremors was mainly noted in both sexes at 750 and 1500 ppm and increased incidence of dilated pupil and excessive salivation were mainly in treated males.

**Neurotoxicity findings in immunotoxicity studies**

In an immunotoxicity study in rats ([REDACTED], 2013), no signs of neurotoxicity signs were noted during the observation period.

**Neurotoxicity findings in endocrine disruption studies**

In the Hershberger bioassay in rats ([REDACTED], 2022), in which orchidopidymectomised male rats were treated at concentrations of 5, 15 and 50 mg/kg bw of dodine, no changes in the autonomic and central nervous systems, in somatomotor activity or in behaviour were noted at examination or at 1-1.5 h post-dosing in any group.

**Conclusion on neurotoxicity**

The collected information indicates that mainly mild effects were observed. Moreover, the effects were mostly reported at high doses or at doses in which clear systemic toxicity was also observed, suggesting dodine has not neurotoxicity potential and, therefore, in this case the RMS does not consider further testing as necessary. A delayed polyneuropathy study is not deemed necessary because the structure of dodine is not related to those capable of inducing delayed polyneuropathy (it is neither an organophosphorus, nor a carbamate compound).

**2.6.8 Summary of other toxicological studies**

**2.6.8.1 Toxicity studies of metabolites and impurities**

**Table 2.6.8.1/01. Summary table of toxicity studies of metabolites**

### Toxicity studies of four metabolites:

Two *in silico* studies have been submitted to address this point. Twelve additional studies have been evaluated in this section to support the toxicological evaluation of guanidine salts. These studies were provided but not evaluated by the applicant and include a range of *in vitro* chromosome aberration, acute toxicity, skin irritation, eye irritation and skin sensitisation studies on guanidine salts.

### Assessment of genotoxicity

No genotoxicity data are available for any of the metabolites. Guanidinium nitrate and guanidinium hydrochloride have been reported negative in an *in vitro* chromosome aberration test (Ishidate and Shigeyoshi, 1977; B.6.8.1.4). This study is pre-guidance and several method deficiencies were identified such as longer exposure period, only 100 metaphases scored, test carried out only without metabolic activation and very limited reporting of results. For this reason, this study is only deemed as supporting information.

The applicant referred to data from the ECHA – REACH Registration dossiers of guanidinium nitrate<sup>2</sup> and guanidinium hydrochloride<sup>3</sup> (CAS No 50-01-1 and CAS No 506-93-4), which is summarised in the following Table 2.6.8.1/02.

**Table 2.6.8.1/02. Summary of data extracted from ECHA on guanidinium salts**

| Compound             | Assay type                    | Result        | Remarks  |
|----------------------|-------------------------------|---------------|--|

No experimental data are available for the metabolites dodecylguanidine-, octylguanidine- and hexylguanidine-carboxylic acids.

*In Silico* prognosis of the metabolites has been carried out for genotoxicity endpoints using a variety of predictive tools (██████████, 2021; B.6.8.1.1 and ██████████, 2020; B.6.8.1.3). The integrated summary predictions and endpoint evaluation according to EFSA guidance 2020 (doi: 10.2903/sp.efsa.2019.EN-1837) are displayed in Table 2.6.8.1/04. Guanidine did not activate any alerts associated with genotoxicity. Similarly, the metabolites dodecylguanidine-, octylguanidine- and hexylguanidine-carboxylic acids did not activate any alerts with the exception of US EPA T.E.S.T *S.Typhimurium* Consensus, Hierarchical clustering and Nearest Neighbour models. These alerts were also activated by the parent compound dodine. Furthermore, the output predictions in Derek Nexus shows all compounds are predicted negative in bacterial mutation (Ames test) and they did not activate any chromosome damage (*in vitro* or *in vivo*) alert (██████████, 2020; B.6.8.1.3).

The OECD (Q)SAR Toolbox was used to identify organic functional groups within the metabolites and parent compound (██████████, 2021; B.6.8.1.1). Two main groups were identified: guanidine (both parent and metabolites share it) and guanidine carboxylic acid (only dodecylguanidine-, octylguanidine- and hexylguanidine-carboxylic acids).

Chemical profiling of the parent and metabolites using the OECD (Q)SAR Toolbox shows none of the compounds contain structural features associated with DNA/protein binding and they do not activate any endpoint-specific profiler alert (██████████, 2021; B.6.8.1.1).

In conclusion, based on a weight of evidence approach, guanidine is not expected to be genotoxic. Both experimental data on guanidinium salts and *in silico* predictions do not indicate this compound can be reactive with DNA. Similarly, *in silico* predictions for the metabolites dodecylguanidine-, octylguanidine- and hexylguanidine-carboxylic acids do not indicate these structures have genotoxic potential. These compounds activate the same alerts as the parent compound. Furthermore, these compounds contain an additional carboxylic acid group in the molecule that it is reported not to infer further reactivity with DNA, as reported by Benigni *et al.* in the EFSA publication 2019 (doi: 10.2903/sp.efsa.2019.EN-1598).

### **Assessment of general toxicity**

No data are available for any of the metabolites.

Guanidinium hydrochloride has a harmonised classification:

Acute Tox. 4 (H302)

Eye Irrit. 2 (H319)

Skin Irrit. 2 (H315)

The applicant provided a series of studies with experimental data on guanidinium salts (chloride and nitrate) that have been evaluated and assessed by the RMS (B.6.8.1.5 to B.6.8.1.15). The summary of these data is displayed in the following table 2.6.8.1/03.

**Table 2.6.8.1/03. Summary of available data on guanidinium salts**

| Compound             | Assay type                        | Result  |
|----------------------|-----------------------------------|---|
| Guanidinium chloride | Acute oral toxicity study in rats | LD <sub>50</sub> (oral, rat):<br>556.5 (♂), 474.6 mg/kg bw (♀)    |
|                      | Acute oral toxicity study in mice | LD <sub>50</sub> (oral, mouse) :<br>570.8 (♂), 621.4 mg/kg bw (♀) |
|                      | Skin irritation study             | Irritating to skin  |
|                      | Eye irritation study              | Irritating to the eye   |

| Compound            | Assay type                         | Result  |
|---------------------|------------------------------------|---|
|                     | Skin sensitisation study (Buehler) | Non-sensitiser  |
| Guanidinium nitrate | Acute oral toxicity study in rats  | LD <sub>50</sub> (oral, rat) :<br>989.6 (♂), 729.8 mg/kg bw (♀) |
|                     | Acute oral toxicity study in mice  | LD <sub>50</sub> (oral, mouse) :<br>1105 (♂) 1028 mg/kg bw (♀)  |
|                     | Skin irritation study              | Irritating to skin  |
|                     | Eye irritation study               | Irritating to the eye   |
|                     | Skin sensitisation study (Buehler) | Non-sensitiser  |

*In Silico* prognosis for general toxicity has been carried out using various predictive models (██████████ 2021; B.6.8.1.2 and ██████████, 2020; B.6.8.1.3). The integrated summary predictions and endpoint evaluation according to EFSA guidance 2020 (doi: 10.2903/sp.efsa.2019.EN-1837) are displayed in Table 2.6.8.1/04. Guanidine did not activate any alerts associated with carcinogenicity and reproductive and developmental toxicity or related endpoints. Guanidine activated a hepatotoxicity alert in Vega as a result of experimental data and a hERG Channel inhibition alert in Derek Nexus.

The metabolite dodecylguanidine carboxylic acid did not activate any alerts associated with carcinogenicity and reproductive and developmental toxicity (out of domain) or related endpoints. It was predicted as non-sensitiser in Derek Nexus (negative prediction) although it activated a hERG Channel inhibition alert in Derek Nexus.

The metabolite octylguanidine carboxylic acid did not activate any alerts associated with carcinogenicity and reproductive and developmental toxicity or related endpoints. It was predicted as non-sensitiser in Derek Nexus (negative prediction) although it activated a hERG Channel inhibition alert in Derek Nexus.

The metabolite hexylguanidine carboxylic acids did not activate any alerts associated with carcinogenicity and reproductive and developmental toxicity (out of domain) or related endpoints. This compound activated a hERG channel inhibition alert, a hepatotoxicity alert and a nephrotoxicity rapid prototype alert in Derek Nexus.

The OECD (Q)SAR Toolbox was used to identify organic functional groups within the metabolites and parent compound (██████████ 2021; B.6.8.1.2). Two main groups were identified: guanidine (both parent and metabolites share it) and guanidine carboxylic acid (only dodecylguanidine-, octylguanidine- and hexylguanidine-carboxylic acids).

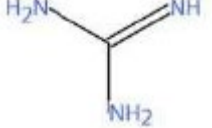

Chemical profiling of the parent and metabolites using the OECD (Q)SAR Toolbox indicates none of the compounds contain structural features associated with general toxicity other than guanidine for repeat dose toxicity (HESS profiler alert) (██████████ 2021; B.6.8.1.2). No profiler alerts associated with general toxicity were activated by dodecylguanidine-, octylguanidine- and hexylguanidine-carboxylic acids.

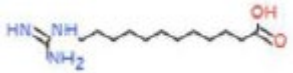

In conclusion, based on available experimental data, guanidine has a lower LD<sub>50</sub> value than dodine, which may indicate this compound is more toxic than the parent compound. Furthermore, guanidine hydrochloride is used as a pharmaceutical drug to treat muscle weakness and fatigue associated with the myasthenic complications in people suffering from Eaton-Lambert syndrome (██████████)<sup>4</sup>. Reported effects in humans include gastrointestinal and nervous system along the neuromuscular system (desired effect as a pharmaceutical drug). Despite no alerts activated for general endpoints other than hERG channel inhibition and hepatotoxicity, guanidine is expected to have different ADME properties in comparison to the parent compound based on physicochemical properties. For this reason, no conclusion can be derived on the general toxicity of this metabolite.

With regards to the remaining metabolites, they have been grouped together as alkyl guanidine carboxylic acid derivatives. *In silico* predictions for dodecylguanidine-, octylguanidine- and hexylguanidine-carboxylic acids indicate they activate a hERG channel inhibition alert in Derek Nexus and this alert is not shared by the parent compound. The metabolite hexylguanidine-carboxylic acid also activates a hepatotoxicity alert and nephrotoxicity alert in Derek Nexus. Due to uncertainties in the ADME properties together with a different toxicological profile with respect to the parent compound, no conclusion can be derived on the general toxicity of these metabolites.

<sup>4</sup> ██████████ (2006) A review of Toxicity and Use and Handling Considerations for Guanidine, Guanidine Hydrochloride and Urea. Report No. PNNL-15747. Pacific Northwest National Laboratory.

This metabolite also activates a hepatotoxicity alert and nephrotoxicity alert in Derek Nexus. Due to uncertainties in the ADME properties together with a different toxicological profile with respect to the parent compound, no conclusion can be derived on the general toxicity of this metabolite.</p> |

### 2.6.8.2 Supplementary studies on the active substance

#### Immunotoxicity

One **immunotoxicity study in rats** was provided by the applicant for the renewal of the active substance dodine. In this study, the administration of dodine in the diet at 0, 200, 500 and 1000 ppm (equivalent to 0, 18, 44, 83 mg/kg bw/day) for 28 days to female rats immunized with SRBC, did not produce adverse effects in survival, clinical signs, haematology, immunological examinations (anti-SRBC IgM titers), absolute and relative spleen and thymus weights and macroscopic examinations. There were statistically significant decreases in bodyweight and bodyweight gain at 1000 ppm. A decrease in anti-SRBC IgM titers at the end of treatment period was seen at 200 ppm, but this was not considered of immunotoxicological relevance because statistical significance and dose-response relationship were not observed. Cyclophosphamide (positive control) produced a statistically significant decrease in the anti-SRBC IgM titers, in the white blood cell count and in absolute and relative spleen and thymus weights compared to control. The **NOAEL for general toxicity** was set at 500 ppm (equivalent to **44 mg/kg bw/day**) based on the decrease in bodyweight and bodyweight gain at 1000 ppm (equivalent to 83 mg/kg bw/day). Under the conditions of this study, which measured immunosuppression, dodine did not produce signs of immunotoxicity. The **NOAEL for immunotoxicity** was considered to be 1000 ppm (equivalent to **83 mg/kg bw/day**) based on the absence of adverse effects in immunotoxicity parameters at the highest dose tested.

With the aim of analysing the effect of dodine on the normal function of the immune system a **detailed review of the existing studies** has been carried out, in which immune-related parameters were analysed from short-term studies, chronic studies and reproductive studies. Furthermore, ADME studies and medical data were also evaluated for this purpose. The distribution of the active substance and its metabolites in tissues may be indicative of its immunotoxic potential, whilst medical data can provide useful information about effects related to inability to fight infection or excessive, poorly controlled responses (as anaphylaxis or autoimmunity).

The most relevant endpoints for this task were selected based on the *Retrospective analysis of the immunotoxic effects of plant protection products as reported in the Draft Assessment Reports for their peer review at EU level* (██████████ 2015, EFSA supporting publication 2015: EN-782) and *Guidance for Immunotoxicity risk assessment for chemicals* (World Health Organization & International Programme on Chemical Safety (2012). *Guidance for immunotoxicity risk assessment for chemicals*. World Health Organization. IPCS harmonization project document; no. 10).

These endpoints were the following:

- Survival and infections, as indicators of potential immunotoxicity, considering that laboratory animals do not use to be exposed to infections.
- From the haematology parameters, total white blood cell counts (WBC) and/or differential counts, as key cell types involved in immune functioning/response.
- Globulin levels in serum, as an indicator of antibody synthesis. If globulin levels were not presented, A:G ratio or serum protein changes were used as surrogates.
- Lymph nodes, as integral parts of the immune system. At least one site of lymph nodes should be included for histopathological examination in most study protocols, but also the finding of lymph nodes with increased size from the clinical observations was included in the analysis.
- Gut associated lymphoid tissue or Peyer's patches, as important tissue in antigen presentation.
- Spleen (weight and histopathology), as organ involved in the maturation of lymphocytes. Altered weights can indicate atrophy or abnormal stimulation. Pathology can indicate altered immune function but can be secondary to other functions of the spleen.
- Thymus (weight and histopathology), as primary organ for T-lymphocyte maturation. Changes in young animals are reported to be more likely to indicate immunotoxicity, as thymus weight varies with the age of the animal, due to its normal age-associated shrinking or involution.
- Bone marrow smear, as reduced cellularity could indicate reduced potential to produce WBC (& RBC).
- Adrenal glands are organ target of cytokines and indeed, ACTH and adrenal steroids regulate the cytokine synthesis. Besides, deposits of immunoglobulins could be observed in adrenal glands. Some autoimmune syndromes as Addison's disease are characterised by adrenal cortex damage.

**Table 2.6.8.2/01: Summary table of animal studies on immunotoxicity**

| Bokotey, S and Turi, Z. (2021) (AS) B.6.9.1  | No specific changes in the health status of the workers involved in dodine production.  | No guideline  |

\* Parameters not analysed, despite they should be reported according to the respective OECD guideline.  
ns: not significant; ncd: not clearly dose-related.

The collected data permit to build an overview on the immunotoxic potential of dodine, considering the following groups of parameters:

#### **General health condition**

The only case in which dead animals seemed to have affected immune system was in the 13-week dietary toxicity study in mice, in which four females at 305 mg/kg bw/day died during the first two weeks, showing lymphoid atrophy of spleen and/or lymphoid atrophy and/or necrosis of the thymus.

Within the limitations of the experiments performed under laboratory conditions, no particular concern about the immune system functioning arose from the analysis of mortality and infections in the rest of the dataset.

#### **Haematology parameters**

White blood cells were increased in the oral 28-day study in rats by gavage, both in males and females at 100 mg/kg bw/day. In these rats, neutrophils were increased while lymphocyte levels were decreased. No effects were observed in the oral 28-day dietary study in rats or in the dermal 28-day study. In the oral 90-day study by gavage, a non-significant decrease in white blood cells was observed in females from 5 mg/kg bw/day and in the oral 90-day dietary study increased neutrophils and slightly decreased lymphocytes were seen at 56 mg/kg bw/day. In the 106-week dietary study in rats, white blood cells and lymphocyte levels were reduced in males at 800 ppm, but only at week 26 sampling. In the T-Cell dependent antibody response (TDAR) assay, white blood cell count was reduced in all treated females, but without dose-dependency

In mice, an increase in segmented neutrophils was seen in males at 350 mg/kg bw/day tested in the 13-week dietary study, while it was not measured in the 78-week study.

In dogs, no effect were observed in the 90-day study, but increments were reported for white blood cells, segmented neutrophils and eosinophils levels in females at 10 mg/kg bw/day tested in the oral 52-week study.

#### **Biochemical parameters**

A decrease in globulin levels in both sexes from 75 mg/kg bw/day and an increase in the A/G ratio in female rats at 100 mg/kg bw/day in the 28-day study by gavage. In the T-Cell dependent antibody response (TDAR) assay, no effects were observed in the antibody response. In the 13-week study in mice, an increase in the A/G ratio was seen in females at 305 mg/kg bw/day. No other effects were observed in any of the rest of the studies available.

#### **Organs and tissues**

**Lymph nodes:** A slight increase in lumbar lymph node hyperplasia (10% at 100 mg/kg bw/day vs 0% in controls) was seen in the dose range finding study teratogenicity study in rats. No other alterations in lymph nodes were detected in the rest of the studies in which they were examined.

**Peyer's patches:** In the 90-day dietary study in rats, hyperplasia of patches of Peyer was seen in one female at 56 mg/kg bw/day. No more data were available.

Spleen:

In rats, an increase in the incidence of lymphoid atrophy of spleen was seen in male and female rats at 200 mg/kg bw/day in the 28-day study performed by gavage. In this study, spleen was not weighed. No histopathological effects were seen in the 28-day dietary study, nor in the 28-dermal study in rats. In the 90-day study in rats, a decrease in the absolute spleen weight was reported in females at 60 mg/kg bw/day and extra medullary haematopoiesis was incremented in males (2/10 at 56 mg/kg bw/day vs 0/10 in control). Spleen histopathology was unaffected in the 106-week study in rats. In the two-generation study, a decrease in the absolute spleen weight was reported only in F2 male and female pups at 800 ppm (the highest dose tested). A reduction in absolute spleen weight was observed in all treated female rats during the T-Cell dependent antibody response (TDAR) assay, but it was not statistically significant.

In the 8-week study in mice, a decrease in the absolute spleen weight was observed in both sexes at 100/1250 ppm. The relative weight was reduced in both sexes from 625 ppm. Cellular depletion and pigment deposit were decreased in one out of five females at 100/1250 ppm. In the 13-week study, reductions were reported in the absolute spleen weight of male mice from 181 mg/kg bw/day and in the absolute and relative spleen weights of females from 223 mg/kg bw/day, and the incidence of lymphoid atrophy was increased in females at 305 mg/kg bw/day (3/10 vs 0/10 in controls). In the 78-week study in mice, a very slight increment in the incidence of small spleens was seen in females (4.3% at 1500 ppm vs 0% in controls).

In dogs, no effects in spleen were observed.

Overall, no clear signs of immunotoxicity were observed from spleen data.

Thymus: Increased incidence of haemorrhage and lymphoid necrosis in thymus was reported for male rats at 200 mg/kg bw/day in the 28-day gavage study, being the dose the highest dose tested with high mortality. In the 90-day dietary study in rats, reductions in the absolute and relative thymus weight were observed, but they were non-statistically significant and histopathology was not affected. In the 106-week study in rats, the incidence of small thymus observed in the necropsy was slightly increased in females (0, 1.4 and 7.1% in 0, 400 and 800 ppm, respectively). In the two-generation study in rats, a reduction in the absolute thymus weight was reported in P male adults and in F2 female pups at 800 ppm. In this study, a slight and non dose-dependent increase in the incidence of red focus area was observed in the F1 male treated adults. The incidence of mottled thymus was slightly increased in F1 female adults at 800 ppm (7% vs 0% in controls). In the T-Cell dependent antibody response (TDAR) assay, a reduction in the absolute thymus weight was observed in females at 1000 ppm.

In mice, lymphoid necrosis in thymus was observed in 4/10 females at 305 mg/kg bw/day vs 0/10 in controls during the 13-week study, in which some females at this dose also showed haemorrhage and lymphoid atrophy. However, in the 78-week study in mice, thymus weight and histopathology were unaffected.

In dogs, an increase in the absolute and relative thymus weight of males was seen from 10 mg/kg bw/day and a decrease was observed in females at 20 mg/kg bw/day during the 90-day study. Moreover, in this last study, reduced thymus size was reported in 1/4 female at 20 mg/kg bw/day during gross necropsy examination and no histopathological effects were reported. In the 52-week study in dog, a very slightly increased incidence of thymus with cysts was observed in both sexes at 20 mg/kg bw/day (4/4 males vs 3/4 in controls; 2/4 females vs 1/4 in controls).

Overall, no clear signs of immunotoxicity were observed from thymus data.

Bone marrow: No alteration in bone marrow was detected in the short-term and long-term studies.

Adrenal gland: In the 28-day study carried out by gavage, increased relative to bodyweight was observed in rats from both sexes at 100 mg/kg bw/day. In this study, in both sexes, slight increases were seen in the incidences of enlarged adrenals at 100 mg/kg bw/day and of haemorrhage at 200 mg/kg bw/day, doses at which mortalities were reported. No effects in adrenals were reported in the 28-day and 90-day dietary studies in rats. In the long-term study in rats, a non-statistically significant reduction in the relative adrenal weight was seen in males from 200 ppm, and very slight increments in enlarged adrenals and adrenals with white mottling in females. In the 2-generations study in rats, increased relative left and right adrenal weights were seen in P female adults at 800 ppm and in F1 female adults from 400 ppm.

In the 13-week study in mice, no effects were observed. In the 78-week study in mice, a decrease in the absolute left adrenal weight was seen in females 750 ppm, and the histopathology was unaffected.

No effects in adrenals were observed in the oral 90-day study in dogs. In the 52-week study, only a slight increase in adrenal glands of males with vacuolization in adrenal cortex was seen from 10 mg/kg bw/day (1/4 vs 0/4 in controls).

Overall, no clear signs of immunotoxicity were observed from adrenals data

**Human data**

Regarding to the available medical data, an occupational report did not show reactions or ill health in any workers.

### ***Conclusion on immunotoxicity***

Based on the available toxicology data, treatment-related changes in the immunotoxic sensitive parameters were observed, but the observations were not considered enough as to conclude that dodine is immunotoxic. In addition, dodine does not belong to a class of chemicals (e.g., the organotins, heavy metals, or halogenated aromatic hydrocarbons) that would be expected to be immunotoxic. Within the scope of this brief analysis, **it can be concluded that dodine is devoid of immunotoxic potential.**

## **2.6.9 Summary of medical data and information**

### **Medical surveillance on manufacturing plant personnel and monitoring studies**

A report is provided in which it is stated that there has not been any specific change in the health status of the workers working with dodine over 20 years (Vol.3, AS, B.6.9.1).

### **Data collected on humans**

No further information was found in the literature search performed for the renewal.

The information available in the Dodine DAR reported one case of oculo-rhinitis due to sensitization to dodine (original study not assessed) and one case of fatal poisoning (but when exposed to a mixture of monocrotophos, dodine and dinocap). Furthermore, several calls to the Belgian Poisoning Center informed about weakness, dizziness and vomiting 10 h after dodine inhalation and ocular irritation (red eye, irritation and tears) after contact of dodine with eyes. Other symptoms were mentioned, but when exposed to mixtures that were not characterised.

### **Direct observations**

There are no direct observations available in the published literature for dodine.

### **Epidemiological studies**

There are no epidemiological studies available for dodine.

### **Diagnosis of poisoning and clinical tests**

There have been no documented cases of human poisoning with dodine. The following signs have been mentioned mentioned by the applicant and in the DAR 2009 (no source citation): By skin contact, skin inflammation is characterised by itching, scaling, reddening, or, occasionally, blistering. Inhalation or ingestion may cause nausea, vomiting, abdominal pains. By eye contact, symptoms of irritation occur.

### **Proposed treatment: first aid measures, antidotes and medical treatment**

No further data necessary with respect to the DAR (2009). If inhaled, remove to fresh air. If not breathing, give artificial respiration. If breathing is difficult, give oxygen. Get medical attention. Do not induce vomiting unless directed to do so by medical personnel. Never give anything by mouth to an unconscious person. If large quantities of this material are swallowed, call a doctor. Loosen tight clothing such as collar, tie, belt or waistband. In case of skin contact, immediately flush skin with plenty of water. Cover the irritated skin with an emollient. Remove contaminated clothing and shoes. Wash clothing before re-use. Thoroughly clean shoes before reuse. Get medical attention. If in contact with eye, check for and remove any contact lenses. Immediately flush eyes with plenty of water for at least 15 minutes. Get medical attention.

No specific treatment is available, treat symptomatically.

## **2.6.10 Toxicological end points for risk assessment (reference values)**

Table 67: Overview of relevant studies for derivation of reference values for risk assessment

| Species                                       | Study (method/type, length, route of exposure)     | Test substance  | Critical effect   | NOAEL   | LOAEL   | Cross reference       |

### 2.6.10.1 Toxicological end point for assessment of risk following long-term dietary exposure – ADI (acceptable daily intake)

The acceptable daily intake (ADI) for humans is normally derived from the NOAEL in the most susceptible species in long-term toxicity studies and applying an appropriate safety factor.

The most sensitive effect in the most sensitive species was found in the one-year toxicity study in dogs ([redacted] (1996). Dodine administration to dogs at the dose of 10 mg/kg bw/day resulted in the necessity of supplemental feeding and therefore the NOAEL of the study was set at 2 mg/kg bw/day.

Therefore, NOAEL of 2 mg/kg bw/day is considered for the calculation of the acceptable daily intake. The safety factor selected was 100 (derived from 10-fold factor for inter-species variability and 10-fold factor for inter-individuals variability) and the ADI for humans was calculated as follows:

$$\text{ADI} = (2 \text{ mg/kg bw/day}) / 100 = 0.02 \text{ mg/kg bw/day}$$

### **2.6.10.2 Toxicological end point for assessment of risk following acute dietary exposure - ARfD (acute reference dose)**

The most relevant study to derive the acute reference dose (ARfD) was the developmental study in rats. The NOAEL in the developmental study in rats was 10 mg/kg bw/day, based on the bodyweight gain and food consumption reduction observed in dams from the first sampling times at 45 mg/kg bw/day.

A safety factor of 100, derived from both 10-fold factor for inter-species variability and 10-fold factor for inter-individuals variability, was considered appropriate. Thus, the ARfD for humans was calculated as follows:

$$\text{ARfD} = (10 \text{ mg/kg bw/day})/100 = 0.1 \text{ mg/kg bw/day}$$

### **2.6.10.3 Toxicological end point for assessment of occupational, bystander and residents risks – AOEL (acceptable operator exposure level)**

The acceptable operator exposure level (AOEL) is defined on the basis of short-term toxicity studies in the most sensitive species and with the application of an appropriate safety factor.

The most sensitive effects in the most sensitive species were found in the one-year toxicity study in dogs (█ (1996). Dodine administration to dogs at the dose of 10 mg/kg bw/day resulted in the necessity of supplemental feeding and therefore the NOAEL of the study was set at 2 mg/kg bw/day.

The RMS considers this NOAEL of 2 mg/kg bw/day as appropriate for the AOEL derivation, with a safety factor of 100 (10-fold factor for inter-species variability and 10-fold factor for inter-individuals variability) and corrected for oral absorption of 39%. Therefore, the AOEL was calculated as follows:

$$\text{AOEL} = (2 \text{ mg/kg bw/day}) * 39 / 100 * 100 = 0.008 \text{ mg/kg bw/day}$$

### **2.6.10.4 Toxicological end point for assessment of occupational, bystander and residents risks – AAOEL (acute acceptable operator exposure level)**

Since an ARfD has been set, also an AAOEL is proposed in this RAR. The most relevant study to derive the ARfD was the developmental study in rats, in which the NOAEL was 10 mg/kg bw/day, based on the bodyweight gain and food consumption reduction observed in dams from the first sampling times at 45 mg/kg bw/day.

A safety factor of 100, derived from both 10-fold factor for inter-species variability and 10-fold factor for inter-individuals variability, was applied and a correction was made for oral absorption of 39%. The AAOEL was calculated as follows:

$$\text{AAOEL} = (10 \text{ mg/kg bw/day}) * 39 / 100 * 100 = 0.04 \text{ mg/kg bw/day}$$

## **2.6.11 Summary of product exposure and risk assessment**

### **RMS conclusions**

#### **➤ OPERATOR**

**According EFSA model, operator exposure to Dodine 544 SC (1,25-1,65 L/ha) from tractor mounted air assisted sprayer application outdoor to high crops is below the AOEL and AAOEL with the use of workwear (arms, body and legs covered) and chemical protective gloves during mixing/loading and application and closed cabin.**

**However, a safe use for the operator to dodine from manual application is not obtained.**

In the opinion of the RMS, as according EFSA Guidance, the penetration factor of the workwear is 10 %, equivalent to a type 6 protective coverall (or the equivalent according EN-ISO 27065 :2017/A1 :2019), in consequence, type 6 protective coverall should be worn instead workwear.

In case of tractor spraying, the specific chemical protective gloves will be used only to handle the application equipment or contaminated surfaces.

Moreover, during cleaning and handling of the equipment, the same PPE as mixing/loading should be used.

Besides, and due to the toxicological classification of the product as Eye Dam. 1; H318, facial protection is recommended during mixing/loading.

#### ➤ WORKER

**According to the results above, the exposure of workers to the active substance dodine is acceptable with the following risk mitigation measures:**

- **For apples and cherries:** Protective coverall, level 1, according EN ISO 27065:2017/A1:2019 standard or workwear (arms, body and legs covered) and closed footwear.
- **For pears:** Protective coverall, level 1, according EN ISO 27065:2017/A1:2019 standard or workwear (arms, body and legs covered) and closed footwear for the first application. For the second application in addition to the above, chemical protection gloves are required for 1 day after application.
- **For peaches:** Protective coverall, level 1, according EN ISO 27065:2017/A1:2019 standard or workwear (arms, body and legs covered) and closed footwear for the first application. For the second application in addition to the above, chemical protection gloves are required for 13 days after application.

*Treated crops should not be re-entered before spray deposits on leaf surfaces have completely dried.*

#### ➤ RESIDENT AND BYSTANDER

**According EFSA model, resident and bystander exposure to DODINE (1,25-1,65 L/ha) from vehicle-mounted application outdoor to high crops is below the AOEL and AAOEL, with the following conditions:**

- **For apples, pears and cherries:** it is necessary to use drift reduction systems, a 10m buffer strip and increase the volume of water up to 1500L/ha.
- **For peaches:** it is necessary to use drift reduction systems, a 10m buffer strip and increase the volume of water up to 1500L/ha. Furthermore, only one safe result is obtained for 1 application.

## 2.7 RESIDUE

### 2.7.1 Summary of storage stability of residues

Three GLP freezer storage stability studies of Dodine residues were performed on the five plant matrices categories: high water, high oil, high starch, high protein and high acid content plant matrices.

The first study (██████████ 1998), previously evaluated in the DAR, was conducted using both, incurred residues (apples/peach/apple pomace) from a magnitude of residue study, and fortified samples (apple juice). The RMS deemed not fully reliable the use of the incurred samples freezed stored for 1.5 year before being used as time 0, as the degradation of the residues, if any, could be not lineal during the storage time. Moreover, procedural recoveries were low in a few cases (apple pomace from 3 months, peach at 15-18 months), so results obtained cannot be considered conclusive. For peach and apple pomace, results were not sufficiently reliable due to the mentioned deficiencies. For apple, results were confirmed by later studies. For apple juice, the stability of dodine residues at ≤ -20°C was demonstrated for at least 18 months (see Table 2.7.1.-1 and vol. 3, B 7.1-1 for further discussion).

The second study (██████████ 2001), also included in the DAR, was deemed acceptable and relevant for the purpose, despite a few minor deviations regarding the requirements of the current OECD guideline. Results showed no significant decline of dodine residues at -18°C for at least 18 months in apple and cherries (see Table 2.7.1.-1).

One additional freezer stability study, investigating the storage stability of Dodine in six matrices from five commodity categories was submitted for the purpose of renewal (██████████ 2022). An interim report was provided during the initial submission (storage up to 12 months), but the final report (up to 24 months) is now available to the RMS and included in the evaluation. The study is considered acceptable according to the OECD guideline recommendations and relevant. Results showed no significant decline of dodine residues at -20°C for at least 24 months in the following matrices: apple fruits, beans, carrots, olives and orange (peel/pulp), representing

respectively, the five categories of high water, high protein, high starch, high oil and high acid commodities (OECD guideline 506) (see Table 2.7.1.-1).

According to the OECD guideline 506, "If residues are shown to be stable in all commodities studied, a study on one commodity from each of the five commodity categories is acceptable. In such cases, residues in all other commodities would be assumed to be stable for the same duration of time under the same storage conditions". Therefore, it can be assumed that dodine is stable at least for 24 months in freezer conditions (-18°C/-20°C) in all plant commodities.

Furthermore, a freezer storage stability study was recently performed in honey. The study followed the current guideline and demonstrated stability of residues in a 6 months storage period at ≤ -18°C. Please refer to Table 2.7.1.-2 and vol. 3, B 7.1/3.

**Table 2.7.1.-1. Storage stability periods for the active substance dodine in plant matrices**

| CATEGORY              | Commodity studied | Periods of stability (months) | Ref.            |
|-----------------------|-------------------|-------------------------------|-----------------|
| High water content    | Apple             | 24                            | [REDACTED] 2022 |
|                       | Cherry            | 18                            | [REDACTED] 2001 |
|                       | Peach*            | 18                            | [REDACTED] 1998 |
| High oil content      | Olives            | 24                            | [REDACTED] 2022 |
| High protein content  | Beans (dry)       | 24                            |                 |
| High starch content   | Carrot            | 24                            |                 |
| High acid content     | Orange peel       | 24                            |                 |
|                       | Orange pulp       | 24                            |                 |
| Processed commodities | Apple juice       | 18                            | [REDACTED] 1998 |
|                       | Apple pomace*     | 18                            |                 |

\* results not considered fully reliable by the RMS due to some deficiencies of the study (see vol. 3, point B.7.1)

**Table 2.7.1.-2. Storage stability periods for the active substance dodine in honey**

| CATEGORY | Commodity studied | Periods of stability (months) | Ref.            |
|----------|-------------------|-------------------------------|-----------------|
| Other    | Honey             | 6                             | [REDACTED] 2020 |

## 2.7.2 Summary of metabolism, distribution and expression of residues in plants, poultry, lactating ruminants, pigs and fish

### 2.7.2.1. Plants

The metabolism of Dodine was investigated in three crops, belonging to the category of fruits: apple, strawberry, pecan nuts (table 2.7.2.-1) using <sup>14</sup>C-dodine labelled in the guanidine carbon. These studies were previously evaluated in the DAR. Although some shortcomings have been identified according to the current guidelines, they are considered relevant for the purpose of renewal (for further discussion see vol. 3, point B.7.2.1.).

**Table 2.7.2.-1. Summary of the metabolism studies in plants**

| Crop groups | Crop(s)    | Application(s)                 | Sampling (DAT)   | Comment/Source  |
|-------------|------------|--------------------------------|--|---|
| Fruit crops | Apple      | 3 x 3.026 kg a.s./ha<br>Foliar | 142 DAT1 – 1st harvest<br>175 DAT1 (33 DAT2) – 2nd harvest<br>183 DAT1 (7 DAT3) – 3rd harvest                                  | Radiolabelled active substance:<br>[ <sup>14</sup> C]dodine (guanidine carbon)<br>([REDACTED] 1992) |
|             | Strawberry | 4 x 3.026 kg a.s./ha<br>Foliar | 28 DAT1- 1st harvest<br>42 DAT1 (14 DAT2) - 2nd harvest<br>62 DAT1 (14 DAT3) - 3rd harvest<br>102 DAT1 (14 DAT4) - 4th harvest | Radiolabelled active substance:<br>[ <sup>14</sup> C]dodine (guanidine carbon)<br>([REDACTED] 1993) |

|  |       |                              |  |   |
|--|-------|------------------------------|--|---|
|  |       |                              |  |   |
|  | Pecan | 3 x 5.7 kg a.s./ha<br>Foliar | 63 DAT1- 1st harvest<br>112 DAT1 (49 DAT2) – 2nd harvest (not analyzed)<br>121 DAT1 (9 DAT3) – 3rd harvest | Radiolabelled active substance:<br>[ <sup>14</sup> C]dodine (guanidine carbon)<br>(██████████ 1998) |

**Apple** trees were treated 3 times with <sup>14</sup>C-Dodine at a rate of 3.026 kg a.s./ha. The foliar application covers that proposed for the representative uses (~5 N the total seasonal rate and 3.4 N each treatment, respecting the cGAP: 2 x 900 g a.i./ha). The first application was carried out at bud break (~BBCH 07), the second at immature fruit stage (~BBCH 71-79), and the last, 7 days before final harvest of mature apples (~BBCH 85-87).

Sampling at three different periods were conducted; for the first one (142 DAT1 and before the 2<sup>nd</sup> application), residue levels were so low that no characterization/identification of fractions was conducted. The 1<sup>st</sup> application was carried out at bud break, prior to the presence of fruits, so the first harvested apples assimilated radiocarbon only by translocation. Translocation experiments performed showed some radioactivity in the leaves from designated branches, but only trace amounts in the various apple matrices (rinsate, pulp, and peel).

The rinse of fruits from the 2<sup>nd</sup> and 3<sup>rd</sup> harvested fruits contained higher levels of radioactivity than the 1<sup>st</sup> sampling: 10.5% of TRR (0.153 mg/kg) for the 2<sup>nd</sup> and 12.0% of TRR (0.18 mg/kg) for the 3<sup>rd</sup> harvest, and the majority of the TRR was detected in the peel (83 and 82.3% TRR for the 2<sup>nd</sup> and 3<sup>rd</sup> harvest, respectively), as fruits were present during the applications.

In immature apples (2<sup>nd</sup> harvest, 33 DAT2), only Dodine (78.2% of TRR) was identified. Besides Dodine, no other component was found at >10% TRR. Several unknown minor fractions (<0.05 mg/kg) were found and one not identified fraction (4.78% of TRR, 0.07 mg/kg) was detected in peel.

In mature apples (3<sup>rd</sup> harvest, 7 DAT3), only Dodine (87.2% of TRR) and tentatively <sup>14</sup>C-guanidine (1.13% TRR, 0.017 mg/kg) in the peel were identified. Besides Dodine, no other component was found at >10% TRR or >0.01 mg/kg. More than 4 components in the pulp and 24 in the peel were detected with values <0.01 mg/kg.

**Strawberries** plants were treated 4 times with <sup>14</sup>C-Dodine at a rate of 3.026 kg a.s./ha. The foliar application covers that proposed for the representative uses (~8 N the total seasonal rate and 3.4 N each treatment, respecting the cGAP: 2 x 900 g a.i./ha). The first application was carried out in immature plants, the second 28 days later, the third one 20 days after the second and the last one 40 days later.

Sampling at 4 different periods were conducted, all 14 days after each treatment, except the first one (28 DALA).

Radioactivity was not readily removed from the fruits with water, because less than 6% was found in the rinses. In fruits from plants treated, most of the radioactivity was <sup>14</sup>C-Dodine (81-91%). Several fractions >0.05 mg/kg (<10%) were found; no identification of other components was performed, except urea, which was identified only in the final harvest (6.5% TRR, 0.275 mg/kg), and guanidine, tentatively identified at low levels in mature fruits in the 2<sup>nd</sup>, 3<sup>rd</sup> and 4<sup>th</sup> sampling (<1.58% TRR, <0.107 mg/kg). Numerous minor fractions (<0.05 mg/kg and <1%TRR) were observed in all sampling periods.

Translocation experiments performed showed some movement of radioactivity into growing parts (0.124, 0.412, 0.334, and 0.841 mg/kg, for the 1<sup>st</sup>, 2<sup>nd</sup>, 3<sup>rd</sup> and 4<sup>th</sup> harvested runners, respectively). HPLC analysis of runner extracts supported the presence of urea as a metabolite in strawberries and dodine as a minor component. Translocation of radioactivity into the strawberry runners seems to occur mainly under the urea form.

**Pecan** trees were treated 3 times with <sup>14</sup>C-Dodine at a rate of 5.7 kg a.s./ha. The foliar application covers that proposed for the representative uses (approximately 9.5 N the total seasonal rate and 6 N each treatment, respecting the cGAP: 2 x 900 g a.i./ha). The 1<sup>st</sup> application was carried out when small nuts were present; the 2<sup>nd</sup>, 63 days after the first one, on immature but well developed nuts, and the 3<sup>rd</sup>, 49 days later, on mature nuts before hull crack. Samples were collected immediately before 2<sup>nd</sup> application (63 days after the first application), immediately before 3<sup>rd</sup> application (samples not analyzed) and 9 days after the last application.

Inmature pecans (whole nuts) from trees treated contained 2.152 mg/kg mg/kg of radioactivity. The major radiolabeled peaks from HPLC analysis of immature pecan extracts corresponded to Dodine (45.35% of TRR, 0.976 mg/kg), and guanidine (15.5% of TRR, 0.326 mg/kg). Two other unknown major peaks were detected accounted for 0.200 mg/kg (9.3% of TRR) and 0.288 mg/kg (13.38% of TRR).

In mature pecans (only nutmeat) from trees treated contained 0.114 mg/kg of radioactivity. The major components corresponded to Guanidine (36.0% TRR, 0.041 mg/kg) and Dodine (13.2% TRR, 0.015 mg/kg). Five minor unknown peaks were also detected (<0.003 mg/kg). A fraction of 4.4% of TRR (0.005 mg/kg) was characterized as non-cationic or neutral and 20% of TRR (0.023 mg/kg) was incorporated to the fatty acid fractions.

In the three studies, more applications than intended (3-4) and several intermediate samplings (2-3) were performed. The last sampling of mature fruits of apple and strawberry was made at a PHI of 7 and 14 days after last application, respectively, showing that dodine was only scarcely metabolized (87.2 and 86.7% of dodine, respectively) at these PHIs. Guanidine was only tentatively identified at low levels: 1.1% of TRR (0.017 mg/kg) in apple and 0.4-1.6 % (0.03-0.107 mg/kg) in strawberries. These results could cover the GAP of the representative use on cherry (PHI 14 days).

Longer PHIs were proposed for apple (60 days) and peach (application until BBCH 69, PHI covered by vegetation period). The intermediate samplings in the metabolism studies provide further information concerning metabolism behavior for periods longer than 14 days: for instance, apple samples from the 2<sup>nd</sup> harvest (33 DAT2 and 142 DAT1) showed that dodine is present still at high levels (78.2%) 33 days after the application, and guanidine was not identified. Strawberry samples from the 1st sampling (28 DAT1) showed dodine at levels of 81% and no guanidine identified. Therefore, at these PHIs, it could be concluded that Dodine is still present at high levels.

For pecans, the mature nutmeat corresponds to the edible part and is more representative of the use on tree nuts. However, it should be highlighted that for immature pecans, the whole fruit was analyzed, and not for mature (shell and hulls removed and not rinsed, neither analysed for radioactivity). Therefore, the results for the immature pecan could be considered more extrapolable to the representative uses. Mature nutmeat presented less radioactivity than immature pecans, likely due to absence of the shells and hulls, which could retain the radioactivity. Therefore, the majority of the radioactivity found in mature pecans likely proceeded from the 1<sup>st</sup> application (conducted 121 days before) and so, the high level of dodine degradation observed. This result suggests that, at long term, dodine could be extensively degraded in pecans, and the proportion of guanidine could be considered relevant (although at low absolute levels).

According to the Applicant: "*Dodine was only sparsely metabolized in apples/strawberries. No major metabolites were found, though urea (only in strawberry) and guanidine were tentatively identified as minor metabolites. Urea would arise from Dodine via dealkylation and oxidation. Knowing the biochemistry of urea and guanidine, the C14 in the guanidine moiety of Dodine must have been partially incorporated into natural products. The formation of either urea or guanidine from Dodine is a slow process, whereas the subsequent breakdown of urea and guanidine is fast.*

*In pecans, the results indicate that a low level of applied Dodine reaches the nutmeat fraction of mature pecans. However, most of the parent compound undergoes extensive metabolism to guanidine, and the latter undergoes further metabolism to carbon dioxide and ammonia. Carbon dioxide is assimilated into the metabolic pool. The very high proportion of lipid in the nutmeat is consistent with incorporation of <sup>14</sup>CO<sub>2</sub> into the fatty acid fraction."*

Qualitative differences are observed between apples/strawberry and pecans. In apples and strawberries, Dodine was only sparsely metabolized, whereas in pecans, a degradation of dodine and occurrence of guanidine as major metabolite cannot be excluded at long term. However, the results of the metabolism in mature pecans cannot be easily extrapolated to other fruits, since in mature pecans only nutmeat has been analysed.

Therefore, in order to cover the representative uses on apple and peach (PHI ≥60 days), the RMS deems advisable to submit a new study in another fruit crop (more similar to the representative uses), covering long PHI, in order to clarify the relevance of the metabolite guanidine in these fruits (see point 2.7.3).

No metabolism studies in rotational crops are submitted because the uses intended are in perennial crops.

#### 2.7.2.2. Livestock

From the representative uses, only apple contributes to animal feed as **apple pomace**, which is only fed to **ruminants**. For the evaluation of the metabolism in livestock, a goat metabolism study was evaluated in the DAR. A goat was dosed with dodine in gelatin capsules at a dose corresponding to 0.4 mg/kg bw/day or 10 mg/kg diet (approximately 100 X the maximum dietary burden calculated for beef cattle, see point 2.7.5).

Total radioactive residues (TRR) reached a plateau of 0.014 ppm in the milk during days 3 to 5 of administration. TRRs in the tissues were highest in the liver (0.17 ppm) and kidney (0.11 ppm). Low concentrations were detected

in muscle ( $\leq 0.02$  ppm) and fat ( $\leq 0.008$  ppm).

Dodine was extensively metabolized in the goat (accounting at  $\leq 5.2\%$  of TRR). The major metabolites ( $>10\%$  of TRR) in liver, kidney and muscle were identified as octylguanidine carboxylic acid, hexylguanidine carboxylic acid and urea; also dodecylguanidine carboxylic acid was identified at levels  $<10\%$  of TRR. Taking into account the low levels of radioactivity found in the different tissues, all these metabolites occurred at levels  $<0.05$  mg/kg.

Thus, regarding the metabolic pathway in livestock, it could be concluded that, after initial conversion to a carboxylic acid, the carbon chain is degraded by removal of two carbon units and that urea is produced by cleavage from the carbon chain.

Data on the metabolism of Dodine in poultry, swine or fish is not required since the representative crops are not fed to these animals.

### 2.7.3 Definition of the residue

The results of the plant metabolism studies showed that the parent compound dodine was identified as the major fraction of the residue (apple and strawberry), accounting for  $\sim 87\%$  of TRR at PHI 7 and 14 days, and 78-80% of TRR at  $\sim 30$  days after treatment. For pecans, dodine is still at high levels in immature ones (45% of TRR) and decreased to 13% of TRR in mature ones.

Based on the metabolism studies summarised above, the **residue definition for monitoring purposes for plants** is proposed as *Dodine*, as it is considered a good marker. Monitoring validated methods (LC-MS/MS) are available for matrices with high water (LOQ 0.05 mg/kg), high acid (LOQ 0.01 mg/kg), high oil content (LOQ 0.01 mg/kg) and dry commodities (LOQ 0.01 mg/kg). An ILV is also available for all four matrices.

Identified degradation products were guanidine and urea (only in strawberry):

- Guanidine, was tentatively identified in very low levels in apple (1.1% of TRR, 0.017 mg/kg), and strawberry ( $<1.6\%$  of TRR,  $<0.107$  mg/kg). On the other hand, it was detected at high levels in pecans (15% of TRR, 0.326 mg/kg and 36% of TRR, 0.041 mg/kg for immature and mature pecans, respectively).
- Urea was found at 6.4% (0.27 mg/kg) only in strawberry samples taken 14 days after the 4th application.

Regarding the toxicological evaluation of metabolite guanidine, the tox. experts concluded the following:

*"Based on a weight of evidence approach, guanidine is not expected to be genotoxic. Both experimental data on guanidinium salts and in silico predictions do not indicate this compound can be reactive with DNA".*

General toxicity: *"based on available experimental data, guanidine has a lower  $LD_{50}$  value than dodine, which may indicate this compound is more toxic than the parent compound.... Despite no alerts activated for general endpoints other than hERG channel inhibition and hepatotoxicity, guanidine is expected to have different ADME properties in comparison to the parent compound based on physicochemical properties. For this reason, no conclusion can be derived on the general toxicity of this metabolite".*

No toxicological information is available for the other metabolite identified, urea (found in strawberry only). However, as urea is already classified as a substance included in Annex IV of Reg. 396/2005 (substances for which no MRL is needed), and no toxicological reference values are established, it can be excluded from further considerations.

For **risk assessment purposes in plants**, the **residue definition** was proposed as *Dodine* in the first inclusion of the active substance, based on the same metabolism studies. Guanidine was found in proportions  $>10\%$  only in one commodity among those studied (pecan), and corresponding to low absolute levels (0.041 mg/kg, study conducted at 9.8 N the total seasonal rate); in addition, it was only tentatively identified and at low levels in the metabolism studies in apples and strawberry. As commented above, the results for the mature pecan could be considered not easily extrapolated to the representative uses apple and cherry. Radioactive residues were low in mature pecans (nutmeat), maybe due to the fact that the residues remained retained in the hull and shell.

Four residue trials evaluated in the context of an art 10 MRL application of dodine (*EFSA-Q-2021-00390*), were also analysed for the metabolite guanidine (see point point 2.7.4.4 and vol. 3, point B.7.3.5, study 3). The RMS included this use in the dRAR as supportive information, for a more comprehensive discussion on the residue definition for risk assessment.

Results obtained supported the fact that most of residues remained retained in the hull: in all trials, residues of dodine and guanidine in hulls were far higher than in nutmeat. Levels of guanidine in nutmeat were below the LOQ (1 mg/kg). It must be highlighted that this LOQ was high. According to the study report, the high LOQ was due to the

background levels found in all control samples assayed, being guanidine a natural organic compound found widely in nature in plants and animals, and no other appropriate source of control samples could be found. Moreover, since dodine was not detected in any untreated sample, at any PHI, it is expected that guanidine is naturally present in the plant and not as a metabolite of Dodine. In hulls, residues of guanidine in untreated and treated plants could be considered similar. In nutmeat, however, as the LOQ was so high, there is no clear evidence that guanidine levels in untreated plants were similar as in treated. Moreover, no storage stability data of guanidine are available to validate these results.

Therefore, considering that:

- guanidine has a lower LD<sub>50</sub> value than dodine, which may indicate this compound is more toxic than the parent compound; it is expected to have different ADME properties in comparison to the parent compound based on physicochemical properties, so no conclusion can be derived on its general toxicity,
  - guanidine was found in high proportions in the metabolism study in pecans (15% of TRR, 0.326 mg/kg and 36% of TRR, 0.041 mg/kg for immature and mature pecans, respectively).
  - the presence of guanidine in the nutmeat as a consequence of the dodine treatment cannot be excluded due to the high LOQ, in the supervised residue trials on almonds (art 10 MRL application), therefore, no data are available to compare the background levels in nutmeats with the levels in treated plants,
  - no storage stability data are available to validate the guanidine results in the supervised residue trials on almonds,
- the RMS would propose (as suggested with Co-RMS) a preliminary “**tentative**” **separate residue definition for risk assessment for guanidine**, pending the submission of general toxicological data and/or further residue data (validated with adequate storage stability data) to exclude the presence of guanidine in the edible part as a consequence of the treatment with dodine. Nevertheless, the RMS considered this proposal more relevant for tree nuts, bearing in mind the metabolism studies in apple and strawberries and taking into account the morphological differences of that group, since the edible part in tree nuts (seed) is not the same as in other fruits.

For **livestock**: The animal dietary burden reaches the trigger value of 0.004 mg/kg bw/day only for beef cattle (see point 2.7.5). The calculated dietary burdens for dairy cattle and sheep are below the trigger value of 0.004 mg/kg bw/day. The representative crops are not fed to poultry and swine.

Regarding the main metabolites found in the livestock metabolism study (goat), the tox. expert concluded:

*- "In silico predictions for the metabolites dodecylguanidine-, octylguanidine- and hexylguanidine-carboxylic acids do not indicate these structures have genotoxic potential. These compounds activate the same alerts as the parent compound. Furthermore, these compounds contain an additional carboxylic acid group in the molecule that it is reported not to infer further reactivity with DNA".*

*General tox: "With regards to the remaining metabolites, they have been grouped together as alkyl guanidine carboxylic acid derivatives. In silico predictions for dodecylguanidine-, octylguanidine- and hexylguanidine-carboxylic acids indicate they activate a hERG channel inhibition alert in Derek Nexus and this alert is not shared by the parent compound. The metabolite hexylguanidine-carboxylic acid also activates a hepatotoxicity alert and nephrotoxicity alert in Derek Nexus. Due to uncertainties in the ADME properties together with a different toxicological profile with respect to the parent compound, no conclusion can be derived on the general toxicity of these metabolites".*

Considering the N rate (100 X) of the goat metabolism study and the low levels of radioactivity found in the different tissues and milk, it is expected that the levels of the metabolites identified in edible tissues would be very low at the dietary intake calculated. Furthermore, as the intake calculated was ≤ the trigger value of 0.004 mg/kg bw/day, no further data are considered necessary and the RMS would propose *Dodine* as **residue definition** by default in commodities of **animal** origin (for **monitoring** and **risk assessment**).

## 2.7.4 Summary of residue trials in plants and identification of critical GAP

The representative uses considered in this application are the uses in apple/pear, cherry and peach.

### 2.7.4.1. Apple

According to SANTE/2019/12752, a total of 8 trials in N-EU and 8 trials in S-EU are required to evaluate the residue

levels in apple and pear, and data on apple can be extrapolated to pear. A total of 23 independent supervised residue trials (12 for N-EU and 11 for S-EU) have been submitted to support the representative critical GAP of Dodine in apple/pear.

The critical GAP for the intended use relevant for consumers is 2 applications of 680 g as/ha, interval 21 days and PHI 60 day on apple in field (SEU, CEU, NEU).

All trials were done in apples with 2 two applications at a target rate of 0.68 kg a.s./ha and a PHI of 60 days. Six of these trials were already evaluated for the first EU Review of Dodine (Portugal, 2009). Within the DAR further trials were evaluated, but they were performed with a number of applications not fitting the GAPs of the representative uses for the renewal (most of them higher number of applications); therefore, they were not considered supportive anymore by the Applicant and were not submitted for the renewal purpose.

Therefore, new trials for the active substance renewal are submitted in order to complete the data set of at least 8 trials N-EU and 8 trials S-EU. All trials complied with the intended uses ( $\pm 25\%$ ), however, the interval between applications (6-8 days) was more critical ( $> \pm 25\%$ ) than that proposed (minimum 21 days), so likely leading to higher residues due to the cumulative effect. However, it should be taken into account that the PHI is long (60 days), and therefore, the level of residues may not be so affected by the interval between applications, as with shorter PHIs. An explanation has been requested from the Applicant, and the justification provided is inline with the RMS considerations. Therefore, despite this deviation, the trials can be considered to support the representative use on apple and extrapolate to pear.

Total residues varied between 0.031 mg/kg and 0.474 mg/kg. The calculated values for STMR, HR and MRL are included in table below (see Table 2.7.4.1-1).

The Applicant proposes to combine NEU and SEU data sets, since populations were found similar according to Mann-Whitney-U test. However, the RMS does not agree with this approach, since MRL calculated from both data sets differed and, according to the technical guideline SANTE/2019/12752, “Combining NEU and SEU residue trials to derive an MRL proposal for one crop/commodity: ... *the MRL proposals derived for the individual data sets should fall into the same or a neighbouring MRL class.*”

**Table 2.7.4.1-1 Summary of results of apple residues trials**

| Matrix                       | Region | Residue Data (mg/kg)   | STMR (mg/kg) | HR (mg/kg)  | Rounded OECD-MRL (mg/kg) | Current MRL (Reg (EU) n° 2022/1290) |

#### 2.7.4.2. Cherry

According to SANTE/2019/12752, a total of 8 trials in N-EU and 4 trials in S-EU are required to evaluate the residue levels in cherry. The representative critical GAP in cherry is 2 applications (minimum interval 21 days) of 0.68 kg a.s./ha from BBCH 60 till 14 days before harvest. Applications proposed after harvest would be less critical, as the consumable part is not present anymore.

In the framework of this application it is referred to a total of 14 NEU and 9 SEU supervised residue trials, the majority evaluated in the DAR:

- 9 NEU and 6 SEU trials were performed with a GAP of 2 applications (int. 6-9 days) of 0.68-0.8 kg a.s./ha and PHI 14 days;
- 5 NEU and 4 SEU trials with 3 applications of 0.8 kg a.s./ha, PHI 14 days.

The trials conducted with 2 applications complied with the intended uses ( $\pm 25\%$ ) regarding application rate, number of applications, growth stage at application and type of formulation. However, the interval between applications (6-9 days) was more critical ( $> \pm 25\%$ ) than that proposed (minimum 21 days), so likely leading to higher residues due to the cumulative effect. Considering the short PHI of the intended use (14 days), there is no evidence that the first application did not contribute to the final residue levels in fruits with a shorter interval, so these trials were not fully compliant with the cGAP and were not considered relevant (for further discussion please see vol. 3, point. B.7.3.).

Trials performed with 3 applications do not correspond exactly to the intended GAP regarding the number of applications. However, since the 1st application was applied before the consumable part of the crop is present, it may be expected that the first application will not have a considerable effect on the residue level and the RMS considers these trials relevant (5 NEU and 4 SEU) (application rate within  $\pm 25\%$  deviation, acceptable according to SANTE/2019/12752). Among these trials, only 2 NEU and 3 SEU are considered independent and valid. Therefore, 6 further NEU and 1 SEU trials would be necessary to support the representative use on cherry in both zones.

The calculated values for STMR, HR and MRL (provisional) are included in table below (see Table 2.7.4.2-1).

**Table 2.7.4.2-1 Summary of results of cherry residues trials**

| Matrix | Region | Residue Data (mg/kg)   | STMR (mg/kg) | HR (mg/kg)  | Rounded OECD-MRL (mg/kg) | Current MRL (Reg (EU) n° 2022/1290) |
|--------|--------|--|--------------|-------------|--------------------------|-------------------------------------|
| Cherry | NEU    | RD Mo/RA1: "dodine"<br>0.7, 0.7<br>RD RA 2 (tentative) "guanidine": --         | -            | -           | -                        | 3                                   |
|        | SEU    | RD Mo/RA1: "dodine"<br>0.77, 0.46, 0.56<br>RD RA 2 (tentative) "guanidine": -- | <b>0.56</b>  | <b>0.77</b> | <b>2<sup>1</sup></b>     |                                     |

<sup>1</sup> available data not sufficient to estimate a robust MRL

### 2.7.4.3. Peach

According to SANTE/2019/12752, a total of 4 trials in N-EU and 8 trials in S-EU are required to evaluate the residue levels in peach. The representative critical GAP is 2 applications (interval 21 days) of 0.9 kg a.s./ha up to BBCH 69 (PHI covered by the vegetation period). Applications proposed from 50% leaf falling till after leaf falling (approx. BBCH 95-97) would be less critical, as the consumable part is not present anymore.

A total of 16 new supervised trials (8 S-EU and 8 N-EU) are available, performed according to the representative critical GAP. All trials complied with the intended uses ( $\pm 25\%$ ), however, the interval between applications (5-8 days) was more critical ( $> \pm 25\%$ ) than that proposed (minimum 21 days), so likely leading to higher residues due to the cumulative effect. However, bearing in mind that applications were conducted before the presence of the consumable part, that PHI are long (86-150 days), and that residues were below the LOQ in almost all cases (at normal commercial harvest), the RMS considers the trials valid and compliant with the cGAP proposed and sufficient to support the representative use on peach.

Total residues of dodine varied between  $< 0.01$  mg/kg and 0.01 mg/kg. The STMR and HR was 0.01 mg/kg. The calculated values for STMR, HR and MRL are included in table below (see Table 2.7.4.3-1).

**Table 2.7.4.3-1 Summary of results of peach residues trials**

| Matrix | Region | Residue Data (mg/kg)  | STMR (mg/kg) | HR (mg/kg) | Rounded OECD-MRL (mg/kg) | Current MRL (Reg (EU) n° 2022/1290) |

|--|-----|---|------|------|-------------|--|

#### 2.7.4.4. Additional data (almond)

The use on almond is being evaluated in the context of an art 10 MRL application of dodine (EFSA-Q-2021-00390). The RMS included this use in the dRAR as supportive information, for a more comprehensive discussion on the residue definition for risk assessment. The assessment performed by ES as EMS in the MRL application was as follows:

According to SANTE/2019/12752 almond is not reported as a major crop. Therefore, according to Reg 283/2013 the minimum number of trials should be 4 for almond. A total of 4 supervised outdoor residue trials on almonds were initially submitted, conducted at the intended GAP ( $\pm 25\%$ ) in Southern Europe (Spain and Portugal) in 2016-2017. The intended critical GAP for the MRL application was 2 applications (interval 14-28 days) of 0.68 kg a.s./ha (PHI 30 days). Trials were considered acceptable in that framework.

According to EFSA (data requirements identified for EFSA-Q-2021-00390): "New almonds residue trials submitted in the context of this dossier are analysed for levels of parent dodine, only. Noting that the relevance of the metabolite guanidine in tree nuts was flagged in the art 12 review ("its potential inclusion into the RD shall be evaluated in the context of future applications on tree nuts and a final decision taken", EFSA 2015), residue trials simultaneously analysed for the parent dodine and its metabolite guanidine in almonds according to the intended uses are required.... This information is required to conclude on the relevance of metabolite guanidine for the residue definition(s) for enforcement and/or risk assessment".

After the EFSA request, 4 additional residue trials were provided. These trials were carried out in 2022 at the intended GAP ( $\pm 25\%$ ) and, besides dodine, metabolite guanidine was also determined (for further assessment extracted from the MRL application, please see vol. 3, B.7.3.5).

The calculated values for STMR, HR and MRL are included in table below (see Table 2.7.4.4-1).

**Table 2.7.4.4-1 Summary of results of almond residue trials**

| Matrix | Region | Residue Data (mg/kg)  | STMR (mg/kg) | HR (mg/kg) | Rounded OECD-MRL (mg/kg) | Current MRL (Reg (EU) n° 2022/1290) |
|--------|--------|---|--------------|------------|--------------------------|-------------------------------------|
| Almond | SEU    | <b>RD Mo/RA 1 : "dodine"</b><br>2 x <0.01, 2 x 0.04, 2 x 0.05, 0.07, 0.08 | 0.05         | 0.08       | <b>0.15</b>              | 0.01*                               |
|        |        | <b>RD RA 2 (tentative): "guanidine":</b> 4 x <1*                          | <1           | <1         | -                        | -                                   |

\*LOQ: 1 mg/kg

further storage stability data would be necessary to validate the data of guanidine

Results obtained supported the fact that most of residues remained retained in the hull: in all trials, residues of dodine and guanidine in hulls were far higher than in nutmeat. Levels of guanidine in nutmeat were below the LOQ (1 mg/kg). It must be highlighted that this LOQ was high. According to the study report, the high LOQ was due to the background levels found in all control samples assayed, being guanidine a natural organic compound found widely in nature in plants and animals, and no other appropriate source of control samples could be found. Moreover, since dodine was not detected in any untreated sample, at any PHI, it is expected that guanidine is naturally present in the plant, and not as a metabolite of Dodine. In hulls, residues of guanidine in untreated and treated plants could be considered similar. In nutmeat, however, as the LOQ was so high, there is no clear evidence that guanidine levels in untreated plants were similar as in treated. Moreover, no storage stability data of guanidine are available to validate these results.

#### 2.7.5 Summary of feeding studies in poultry, ruminants, pigs and fish

Among the representative uses, only apple can be used to fed livestock and should be considered to estimate the dietary burden for livestock.

The dietary burden calculation was carried out according to the latest EFSA model (EFSA dietary burden calculator (Animal model 2017.xls). Estimation of animal intakes and HR, STMR and MRL calculations for products of animal origin, September 2015). Residue values used for calculation are presented in Table 2.7.5-1. The STMR value for apple of Dodine of the most critical SEU data set was used. The median processing factor of 2.6 for apple pomace was applied.

The calculated dietary burdens for dairy cattle, sheep, pig, and poultry are below the trigger value of 0.004 mg/kg bw/day. For beef cattle, the dietary burdens are calculated to be at the trigger value of 0.004 mg/kg bw/day. Results are presented in Table 2.7.5-2.

**Table 2.7.5-1 Input values for dietary burden calculation**

| Commodity                             | Median dietary burden |                 | Maximum dietary burden |                 |
|---------------------------------------|-----------------------|-----------------|------------------------|-----------------|
|                                       | Input value [mg/kg]   | Comment         | Input value [mg/kg]    | Comment         |
| Apple pomace, wet (by-products group) | 0.34                  | STMR x PF (2.6) | 0.34                   | STMR x PF (2.6) |

| Poultry (layer only) |                             |         |          |         |                        |                             |             | No                        |

(a): When several diets are relevant (e.g. cattle, sheep and poultry "all diets"), the most critical diet is identified from the maximum dietary burdens expressed as "mg/kg bw per day".

(b): The most critical commodity is the major contributor identified from the maximum dietary burden expressed as "mg/kg bw per day".

\*No apple pomace is fed to pigs or poultry.

Very low residues were found in the goat metabolism study, which was performed with an intake of 0.4 mg Dodine/kg bw/day, which is 100-fold higher than the calculated burden for beef cattle. Total radioactive residues (TRR) in the goat reached a plateau of 0.01 mg/kg in the milk during days 3 to 5 of administration. Further total radioactive residue levels were 0.17 mg/kg in the liver, 0.11 mg/kg in the kidney, ≤0.02 mg/kg in muscle and ≤0.008 mg/kg in the fat. If these values are recalculated to an intake at the level of the expected dietary burden, the expected residues are far below 0.01 mg/kg. Thus, no relevant residues are expected in commodities of animal origin and a livestock feeding study is, therefore, not required.

### 2.7.6 Summary of effects of processing

One hydrolysis study was submitted, simulating the normal processing practice of pasteurisation, sterilisation and baking/brewing/boiling at 90°C and pH 4 (20 min), at 121°C and pH 6 (20 min), and at 100°C and pH 5 (60 min), using [<sup>14</sup>C]Dodine in buffered solutions. The total recovered radioactivity of all test solutions after thermal processing accounted for 92.9-98.7% of the nominal applied radioactivity.

In all test solutions only [<sup>14</sup>C]Dodine was detected after processing and no degradation products were found. Dodine is therefore considered hydrolytically stable at 90°C and pH 4 (20 min), 121°C and pH 6 (20 min) and 100°C and pH 5 (60 min). Thus, the same residue definitions as for primary crops would apply to processed commodities.

Three apple processing studies were performed. In these studies a total of three independent trials were performed simulating the industrial processing of apples to juice, wet pomace and canned apples. The number of trials is sufficient to derive robust processing factors:

For apple juice single processing factors of 0.09, 0.18 and 0.17 were derived (median value: 0.17). For wet pomace single processing factors of 5.1, 2.6 and 2.1 were calculated (median value: 2.6). In canned apples no residues were detected after canning (residues < LOD) – therefore processing factors were calculated using the LOQ of 0.01. The single processing factors derived are 0.13, 0.17, 0.25 (median 0.17) (See table below 2.7.6.-1).

Processing factor for apple juice may be extrapolated to other pome (pear) or stone fruits (peach).

**Table 2.7.6.-1 Summary of processing factors (representative uses)**

| Processed commodity | Number of studies | Processing Factor (PF) |           |
|---------------------|-------------------|------------------------|-----------|
|                     |                   | Individual values      | Median PF |
| Apples, juice       | 3                 | 0.09, 0.18, 0.17       | 0.17      |
| Apples, wet pomace  | 3                 | 5.1, 2.6, 2.1          | 2.6       |
| Apples, canned      | 3                 | 0.13, 0.17, 0.25       | 0.17      |

### 2.7.7 Summary of residues in rotational crops

Representative uses (apple, cherry, peach) are perennial crops, therefore, data on the metabolism or magnitude of residues in rotational crops are not required

### 2.7.8 Summary of other studies

One study for determination of residues of dodine in phacelia honey under semi-field conditions was submitted.

The representative uses (apple, cherry and peach) are considered melliferous crops. Residues in honey might occur due to the use of Dodine on these melliferous plants during flowering or from non-target plants, as the applications will be during the flowering period from April to September. According to SANTE/11956/2016, a total of 4 trials are required to evaluate the residue levels in honey. Four independent residue trials in phacelia (*Phacelia tanacetifolia*) (2 NEU and 2 SEU) have been submitted.

The critical GAP for the intended uses relevant for consumers is 2 applications of 900 g as/ha. All trials were carried out with 2 applications with a rate per treatment of 0.9 kg a.s./ha, covering the cGAP (1N).

All trials were in Phacelia under semi-field conditions (tunnel trial).

Trials were carried out according to SANTE/11956/2016, with minor deviations and they are considered relevant for the purpose of the renewal of dodine.

Honey specimens were taken for analysis 7-14 days after last application to get mature honey. Residues of Dodine were extracted and final determination was performed by HPLC-MS/MS. Total residues varied between <0.01 mg/kg and 0.12 mg/kg. The calculated values for STMR, HR and MRL are included in table below (Table 2.7.8-1).

An exceedance of the current MRL is expected. The submitted data are sufficient to derive a MRL proposal for the NEU/SEU use. An application for a modification of MRL in honey has been submitted by the applicant.

**Table 2.7.8-1 Summary of results of honey residues trials**

| Matrix | Region  | Residue Data<br>(mg/kg)                       | STMR<br>(mg/kg) | HR<br>(mg/kg) | Rounded<br>OECD-<br>MRL (mg/kg) | Current MRL<br>(Reg (EU) n°<br>2022/1290) |
|--------|---------|---|-----------------|---------------|---------------------------------|---|
| Honey  | NEU/SEU | RD Mo/RA: "Dodine"<br>2 x < 0.01, 0.056, 0.12 | 0.03            | 0.12          | 0.3                             | 0.05*                                     |

### 2.7.9 Estimation of the potential and actual exposure through diet and other sources

A consumer risk assessment was conducted using the last version of the EFSA PRIMO tool, v. 3.1. The toxicological reference values used proposed by the applicant have been reviewed by the RMS and the following values included in table 2.7.9-1 were finally proposed (see vol. 1, point 2.6.10) and used for the risk estimation:

**Table 2.7.9-1. ADI and ARfD for the active substance Dodine**

| End-Point                     | Value             | Study  | Safety factor | Reference       |
|-------------------------------|-------------------|--|---------------|-----------------|
| Acceptable Daily Intake (ADI) | 0.02 mg/kg bw/day | 1-year and 90-day dog studies                        | 100           | dRAR (ES, 2022) |
| Acute Reference               | 0.1 mg/kg bw      | based on body weight gain and food consumption at 45 | 100           | dRAR (ES, 2022) |

|             |  |  |  |  |
|-------------|--|--|--|--|
| Dose (ARfD) |  | mg/kg bw/day in the developmental toxicity study in rats (NOAEL 10 mg/kg bw/day) |  |  |
|-------------|--|--|--|--|

The risk assessment residue definition for plants (and animals, by default) was proposed as: "Dodine" and the conversion factor from monitoring to risk assessment: 1 (see point 2.7.3).

A chronic consumer risk assessment was performed using the current MRLs (Reg. (EU) 2022/1290) for the representative crops and for the animal commodities relevant for the representative uses (bovine, sheep, goat, equine) and the proposed MRL of 0.3 mg/kg for honey, for a tier one assessment. Results are included in table 2.7.9-3 and showed a TMDI of 2-72% (NL toddler, highest contributor, apples) of the ADI.

A refinement using the STMR derived from the magnitude of residue trials in the representative crops (see table 2.7.9-2) was estimated and results were 0.4-15% of ADI (DE child, highest contributor, apples) (table 2.7.9-4). It can therefore be concluded that there is no chronic risk from the consumption of apples/pears, cherries and peaches treated with Dodine according to the intended GAP or from honey.

An acute consumer risk assessment using the current MRLs showed an acute risk for the representative use on pears (1st scenario, see table 2.7.9-5). A refinement, using the Highest Residues for the intended crops according to the input values included in table 2.7.9-2, was assessed. Results showed IESTI values below the ARfD for apples, pears, cherries and peaches (51%, 65%, 37% and 1%, respectively, and 0.4% for honey). (see table 2.7.9-6).

The current MRL was used as input values for cherry, as the number of trials fitting the intended GAP is not sufficient to support the use on cherry and a data gap for further trials is identified (see point 2.7.4.2).

Hence, it can be concluded that there is no acute risk from the consumption of apples/pears, cherries and peaches treated with Dodine according to the intended GAP and from honey.

**Table 2.7.9-2. Input values for the consumer risk assessment (second scenario)**

| Commodity                            | Chronic risk assessment |                           | Acute risk assessment |                           |
|--------------------------------------|-------------------------|---------------------------|-----------------------|---------------------------|
|                                      | Input (mg/kg)           | Comment                   | Input (mg/kg)         | Comment                   |
| apple                                | 0.13                    | STMR x CF (1)             | 0.47                  | HR x CF (1)               |
| pear                                 | 0.13                    | STMR x CF (1)             | 0.47                  | HR x CF (1)               |
| apple, pear juice                    | 0.022                   | STMR x PF (0.17) x CF (1) | 0.022                 | STMR x PF (0.17) x CF (1) |
| cherry <sup>a</sup>                  | 3                       | MRL <sup>b</sup>          | 3                     | MRL <sup>b</sup>          |

| peach, juice                         | 0.0017                  | STMR x PF (0.17) x CF (1) | 0.0017                | STMR x PF (0.17) x CF (1) |
| bovine/sheep/goat/equine commodities | 0.01                    | MRL <sup>b</sup>          | 0.01                  | MRL <sup>b</sup>          |
| milk                                 | 0.01                    | MRL <sup>b</sup>          | 0.01                  | MRL <sup>b</sup>          |
| honey                                | 0.03                    | STMR x CF (1)             | 0.12                  | HR x CF (1)               |

<sup>a</sup> current MRL used as input value for cherry, as not enough trials available to support the use (data gap)

<sup>b</sup> Reg. (EU) 2022/1290

For guanidine, the consumer risk assessment remained open, since no data of residue levels in the representative uses are available, nor toxicological reference values established.

Table 2.7.9-3: Chronic consumer risk assessment of representative uses (EFSA PRIMo, rev. 3.1)

### 2.7.10 Proposed MRLs and compliance with existing MRLs

EU MRLs for dodine are currently detailed in the Regulation (EU) 2022/1290<sup>(a)</sup>. According with the available data no change is proposed for enforcement residue definition, and neither for the LMR of the representative uses and for relevant animal commodities. Regarding the representative use on cherries, available data are not enough to estimate a MRL (a data gap for further trials is identified, see point 2.7.4.2).

A new MRL is proposed for honey. The submitted data are sufficient to derive a MRL proposal for honey for the NEU/SEU use. Risk for consumers unlikely. For guanidine the consumer risk assessment remained open, since no data of residue levels in the representative uses are available, nor toxicological reference values established.

| Code    | Commodity          | Current EU MRL <sup>(b)</sup> (mg/kg) | Proposed EU MRL(mg/kg) |
|---------|--------------------|---------------------------------------|------------------------|
| 0130010 | Apple              | 0.9                                   | No change              |
| 0130020 | Pear               | 0.9                                   | No change              |
| 0140020 | Cherry (sweet)     | 3                                     | No change <sup>c</sup> |
| 0140030 | Peach              | 0.1                                   | No change              |
| 1040000 | Honey <sup>a</sup> | 0.05*                                 | 0.3                    |

<sup>a</sup> an application for a modification of MRL in honey has been submitted by the applicant.

<sup>b</sup> Reg. (EU) 2022/1290

<sup>c</sup> data available not sufficient to estimate a MRL

### 2.7.11 Proposed import tolerances and compliance with existing import tolerances

Not relevant.

## 2.8 FATE AND BEHAVIOUR IN THE ENVIRONMENT

### 2.8.1 Summary of fate and behaviour in soil

#### 2.8.1.1 Route of degradation in soil

The aerobic and anaerobic degradation of dodine was studied under laboratory conditions. The influence of irradiation in the degradation process of dodine was also investigated. A summary is presented in the following table:

**Table 2.8.1.1-1. Summary of route of degradation in soil studies**

#### 2.8.1.1.1 Aerobic degradation in soil

A total of 3 studies were evaluated in order to establish the aerobic route of degradation of dodine in soil. During the first peer review of dodine, two aerobic soil degradation studies under laboratory conditions were considered and were assessed as “acceptable” (██████████, 2006- KCA 7.1.1.1/02-; ██████████ 1997 - KCA 7.1.1.1/03-). For the active substance renewal, a position paper has been submitted, ██████████ (KCA 7.1.1.1/01), assessing the relevance of Cluster M1 observed in the aerobic degradation study by ██████████ (1996). They have been accepted by RMS and their summaries can be found in Dodine DRAR Vol 3 B8, under point B.8.1.1.1.

██████████ (1996) investigated the metabolism of Dodine in two sandy loam soils (UK and USA soils), labelled on the guanidine carbon. Soils were incubated under aerobic conditions at  $25 \pm 1^\circ\text{C}$  and approx. 75% of their 1/3 bar moisture holding capacity in dark for up to 100 days. [ $^{14}\text{C}$ ]Dodine was applied at a rate equivalent to 4.48 kg a.s./ha, exceeding 2.5 times the maximum field rate per crop/season claimed in the GAP of 1.8 kg a.s./ha ( $2 \times 0.9$  kg a.s./ ha). According to the results, dodine degraded to <10% AR after 28 days in both soils. The major degradation products were  $\text{CO}_2$ . Unextractables were less than 3% AR at the end of the study. No accumulation was observed. Volatile radioactivity consisted only of  $\text{CO}_2$  and was 91.8 and 91.2% AR at day 100 for UK and USA soils, respectively. Dodine plus a cluster of minor metabolites were detected in soil extracts. Metabolite cluster M1 was measured at maximums of 9.7 % AR and 5.3 % AR on days 0 and 1, respectively, in the UK soil, and maximums of 7.6 % AR and 5.0 % AR on day 0 and 1, respectively, in the US soil. For all other samplings, cluster M1 was always < 5 % AR in both soils. For the renewal, a position paper, assessing the relevance of Cluster M1 was provided (KCA 7.1.1.1/01).

After detailed evaluation of cluster M1 metabolite, RMS agrees with the applicant that Cluster M1 does not represent a major metabolite for the following reasons:

- It was clearly demonstrated that no relevant metabolites are observed in US soil.
- In UK soil, it is highly unlikely that on day 1, one individual component of cluster M1 reaches a 5 % AR, since it means that such component should represent  $\geq 94.3$  % of the total cluster. It is clear from the chromatogram that the highest peak is itself a composite peak. This was also supported by the results of ██████████ (2001) where a cluster containing multiple peaks at the same RRT was observed. The HPLC profiles of the re-analysed samples in ██████████ (2001) and ██████████ (1996) support the argument of the RMS and the applicant that no relevant metabolites are observed in UK soil.
- It cannot be rejected that the relatively high occurrence at day 0 may be an artefact due to concentration of impurities during sample work up. Assuming that Cluster M1 are formed by impurities, it is noted that the new technical specification for the renewal of dodine have a refined profile of impurities, and none of them have been classified as toxicological or ecotoxicological relevant.
- The components of cluster M1 are transient, accounting for less than 5% AR after 24 hours assuming worst-case situation (highly unlikely), and no observed in any other studied soil at relevant amounts.

In ██████████ (1997), the route of degradation of dodine was determined in three soils (sand, sandy silt loam and clay loam), labelled on the guanidine carbon, and in one additional soil (clay loam), labelled in the [ $^{14}\text{C}$ ]-chain. Soils were incubated under aerobic conditions, at  $20 \pm 1^\circ\text{C}$  and approx. a moisture tension of pF2.5, in dark for up to 120 days.

In the study, the non-volatile compounds that were detected in the soil extracts were seen to comprise Dodine plus a cluster of minor metabolites (‘M1 cluster’). The minor metabolite cluster M1, consisting of up to eleven compounds was measured at maximums of 9.7% AR and 5.3% AR on days 0 and 1, respectively, in the UK soil, and maximums of 7.6% AR and 5.0% AR on day 0 and 1, respectively, in the US soil. Soils were treated at a nominal application rate of 2.6325 kg a.s./ha ( $3 \times 0.8775$  kg a.s./ ha), exceeding the maximum field rate per crop/season claimed in the GAP of 1.8 kg a.s./ha ( $2 \times 0.9$  kg a.s./ ha). In the guanidine labelled experiments there was no metabolite that reached 5% AR at any time and the total of metabolites at the end of the study accounted for less than 1.5% of applied material. In the chain labelled experiment one metabolite reached a level of 5.5% of applied material after one day but thereafter the level decreased and it was not detectable at the end of the study at which time extractable metabolites accounted for only 0.3% of applied radioactivity. The results of the experiment conducted with chain labelled dodine show that the dodecyl moiety of the molecule was also ultimately degraded to carbon dioxide. Incorporation of the partially degraded chain resulted in disappearance of parent material at a similar rate to that seen in

the guanidine labelled experiments but with a slightly delayed evolution of radiolabelled carbon dioxide. Intermediate metabolites were produced in very small quantities and were themselves degraded without a build up of residues remaining associated with the soil.

All in all, it is concluded that dodine is quickly metabolised in soil and its degradation ultimately resulted in a formation of CO<sub>2</sub> without formation of any major metabolite or persistent unextractable residues. The location of radiolabelling in the molecule has no effect on its properties or degradation, and results from studies using either radiolabelling position are comparable.

Degradation of dodine occurred by fragmentation of the molecule in three parts: dodecane, guanidine and acetic acid. The guanidine and the dodecane chain should be rapidly used by soil microflora. The structure of dodine suggest that two mechanism of breakdown are likely. The first would involve removal of the acetate moiety and direct attack on the guanidine group and the second an oxidation mechanism, such as beta oxidation, causing successive reductions in the alkane chain which eventually allows attack on the guanidine group. Either or both these mechanisms maybe in operation in a soil environment.

A proposed metabolic pathway based on the results of both guanidine and chain experiments are presented in **Figure 2.8.1.1.1-1**.

**Figure 2.8.1.1.1-1 – Proposed degradation pathway of dodine in aerobic soil**

#### 2.8.1.1.2 Anaerobic degradation in soil

Applicant considers that exposure to anaerobic conditions is not expected for the representative uses applied for. Taking into consideration the low persistence of dodine in soil (modelling DT<sub>50</sub>= 5.25 d), its immobility in soil ( $k_{oc} > 50000$  L/kg) and the results of ██████████ (2017) relating to the irreversible binding of the active substance to soils, the occurrence of anaerobic or partial anaerobic conditions after spring-summer applications of dodine in orchards is not expected.

However, according to the GAP of the representative formulation of the renewal of the active substance, applications in autumn are claimed for. Therefore, anaerobic conditions during flooding of soils after heavy rainfalls cannot be excluded.

The anaerobic route of degradation of dodine HCl was studied by ██████████ (1993 (KCA 7.1.1.2/01)). This study was already submitted and accepted in the DAR of Dodine (2009) and it is considered as supplementary information for the renewal of the active substance. No new studies are presented by the notifier. Consequently, a data gap for a new anaerobic degradation study conducted according to the current

OECD 307 guideline has been identified in order to comply with EU data requirements (please refer to Regulation (EU) No 283/2013).

█ (1993) investigated the degradation of dodine HCl in a sandy loam soil from Nebraska (UK), under dark, at 25°C, on anaerobic incubated flooded soil. It is noted that the test was conducted at an exaggerated rate of 11.6 kg/ha, adding an uncertainty to the results, since degradation of the test compound could have been affected. Results indicate that the degradation of dodine HCl under anaerobic conditions was extremely slow. The mineralisation to CO<sub>2</sub> was less than 0.1% AR after 12 months. The bound residues increased steadily from 2 % AR at day 0 to 12% at 12 months. Approximately 9% of the 12% were associated with the humin phase, indicating that dodine residues are strongly bound into soil matrix. No mayor transformation products were formed during the study. A polar minor metabolite, identified as a hydroxylated derivative of the parent compound, reached a concentration of 2.89% AR at the end of the study.

**2.8.1.1.3 Soil photolysis**

The photolysis of dodine was studied, by █ 2001 (KCA 7.1.1.3/01), in a sandy loam soil (<sup>14</sup>C-guanidine labelled). This soil photolysis study was already submitted and accepted in the DAR of Dodine (2009) and it is still considered acceptable for the renewal of the active substance.

Soil samples were treated at an equivalent rate of 4.5 kg dodine/ha. The soils were incubated at 25°C and exposed to irradiation from a xenon light source using 12 hours of light and 12 hours of dark cycle for 30 days to simulate natural summer sunlight. The average intensity of light source per day (5850 w/m<sup>2</sup>) was considered equivalent to the maximum sunlight intensity on hot summer day at latitude 50°N. A dark control was included in the experiment.

Results show that Dodine is metabolized by soil microorganisms which ultimately results in the formation of carbon dioxide and several minor metabolites. CO<sub>2</sub> formation accounted for 12 and 14 %AR in the irradiated soil and in the dark control, respectively. Unextractable residues were less than 6% AR. There was one fraction which accounted for aprox. 10% AR on day 1 for irradiated sample (HPLC retention time 23-24 min). This sample was isolated and re-analyzed with a different HPLC conditions and shown to contain multiple peaks. Therefore, no major metabolites were observed in the study.

Both irradiated and dark soils show a similar degradation pattern, indicating that degradation and metabolite formation can be considered independent of irradiation.

The half-life of Dodine was calculated and was found to be 122 and 235 days in irradiated samples and dark control samples, respectively. The slower degradation of Dodine under photolytic conditions than the one observed in aerobic soil metabolism studies could be due to the low water holding capacity of the soil used and also the design of the photolysis study.

According to the results, it can be concluded that photolysis does not play a significant role for Dodine degradation in soil.

**2.8.1.2 Rate of degradation in soil**

The rates of degradation of dodine were evaluated following the recommendations of the FOCUS kinetic guidance.

The rate of degradation of dodine in standard dark aerobic laboratory studies has been determined in 5 different soils at 20/25°C. Dodine degraded rapidly in soil with persistence DT<sub>50</sub> values at 20°C ranging from 2.9 to 17 days (not corrected for moisture) in five soils. DT<sub>90</sub> values ranged from 9.7 to 35.7 days. Degradation generally followed SFO kinetics, with one exception (Sandy loam soil, 95-18, FOMC kinetics) (Table 2.8.1.2-1).

**Table 2.8.1.2-1: Persistence DT<sub>50</sub> values at 20 °C of parent compound, dodine**

| Dodine                    | Dark aerobic conditions –Persistence endpoints |                  |                |                      |                      |                    |                       |                       |

| pH dependence,      |     |         |   | Yes  |                                    |      |                    |

<sup>a)</sup>Measured in water

<sup>b)</sup>Normalised using a Q10 of 2.58 and Walker equation coefficient of 0.7

For modelling purposes, the normalized DT<sub>50</sub> values (20°C and pF2) ranged from 2.93 to 9.25 days with geomean of 5.25 days (Table 2.8.1.2-2). Details of the kinetic evaluation and temperature and moisture normalisation are provided in Vol. 3 CA B8, Point B.8.1.2, Study KCA 7.1.2.1.1/01 (██████████ 2021). The pH dependency of the degradation of dodine was assessed by RMS using software tool pHADe (UBA). According to the results of Kendall's test and the linear fits, degradation of dodine is pH dependent, being faster under basic conditions. In the particular case of dodine, RMS considers that the pH dependence should not be included in the environmental modelling to avoid an increase in complexity of the modelling and overworking. No impact on the risk assessment conclusions from the estimated predicted concentrations in soil, groundwater and surface water is expected. For PECsoil calculation the worst-case DT50 of 17 days (20°C, non-normalized for moisture) was used. For PECsw and PECgw calculations the geomean of 5.25 days was selected, while the normalized DT50 values were in the range of 2.93 to 9.25 days (geomean ± 2-4 days).

Under anaerobic laboratory conditions dodine does not degrade significantly according to a supplementary study conducted at an exaggerated application rate and with an experimental design that deviates from recommendations of OECD 307 guideline. No further data are available and a data gap has been identified for the representative uses where exposure to anaerobic conditions cannot be excluded (autumn applications). Moreover, photolysis does not play a significant role for Dodine degradation in soil.

Studies on field soil dissipation of Dodine are not required since laboratory aerobic soil degradation studies confirmed that the degradation of Dodine is rapid. However, the trials were conducted at locations across the USA. It should be justified that conditions of the field dissipation trials outside EU are representative of agricultural conditions in Europe. Moreover, a revision of the kinetic parameters of this study according to the recent FOCUS degradation kinetic guidance document has not been provided. All in all, the study is considered as supplementary.

### Assessment in relation to the P-criteria

The assessment is done according to the DG SANCO Working Document on "Evidence Needed to Identify POP, PBT and vPvB Properties for Pesticides" (2012, rev. 3).

The criteria for persistence (P) in soil, as stated in Regulation (EC) 1107/2009, are DT50 >120 days for PBT and >180 days for POP and vPvB. When considering laboratory degradation rates, best-fit DT50 values at 20°C for dodine are < 120 days in the 5 available soils.

**Based on all available data, it is concluded that the P-criteria in soil is not fulfilled for dodine.**

#### 2.8.1.3 Mobility

Three individual studies for adsorption and desorption of the active substance are summarised in Table 2.8.1.3-1. Two studies are experimental tests (KCA 7.1.3.1.1/01 and KCA 7.1.3.1.1/03) and one study is an expert statement (KCA 7.1.3.1.1/02).

a) Spiked with guanidine-labelled Dodine

b) Measured in 0.01 M CaCl<sub>2</sub>

c) K<sub>d</sub> and K<sub>oc</sub> were not measured

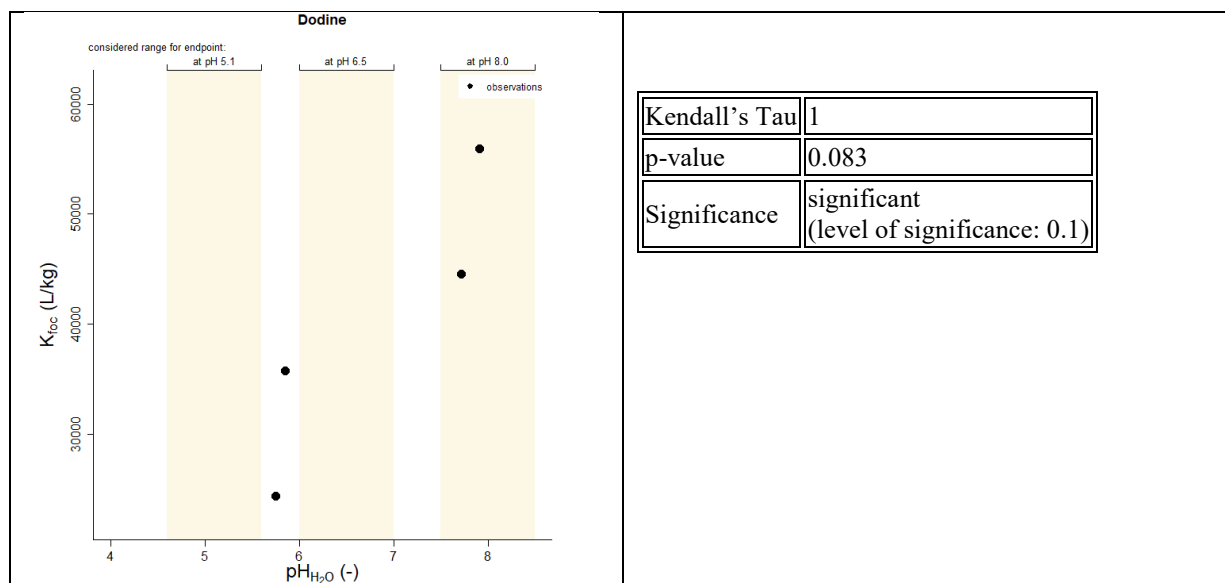

One study on absorption and desorption of Dodine hydrochloride (1991 - KCA 7.1.3.1.1/03-) was already submitted and accepted in the DAR of Dodine (2009). The study was performed with four different soils with UK origin (a sand, a sandy loam, a clay loam and a silt loam soil) that covered a range of organic carbon contents between 0.05% and 2.10%, a range of pH from 6.4 to 7.6 and a clay content from 4% to 38%. Due to several deficiencies identified in the study, it is considered that the adsorption has been overestimated. This is also confirmed when results of (2017) and (2017) and (1991) are compared. **Therefore, RMS considers that the study is not valid to be used in the environmental risk assessment.**

The applicant has provided a new adsorption/desorption study in soil for Dodine for the purpose of renewal (KCA 7.1.3.1.1/02). In this study the advanced test was performed using four sterilised soils at a soil-to-solution ratio of 1:25 and five test concentrations covering two orders of magnitude (0.01 – 1.00 µg/mL). In addition, an evaluation of the data available from this study has been performed according to the OECD 106 Evaluator's Checklist (2017) confirmed the study was acceptable and the study meets or exceeds all established quality criteria (KCA 7.1.3.1.1/03). The calculated adsorption coefficients normalised to organic carbon content, K<sub>FOC(ads)</sub>, range from 24376 to 55905 mL/g (geometric mean: 38395 mL/g).

The results of both batch adsorption studies (1991, and 2017) indicate that dodine shows a strong adsorption to soil and can be considered immobile.

The pH dependency of the adsorption of dodine was assessed by RMS using software tool pHADe (UBA). According to the results of Kendall's test, adsorption of dodine seems to be pH dependent, being higher under basic conditions. However, the test was significant at 0.1 % level of significance (p-value= 0.083) and only 4 data are available. Without further data it is difficult to conclude on the pH dependence of the active substance since its physical and chemical properties do not explain this behaviour. RMS position is that the data requirements are fulfilled and that no further information on pH dependence of adsorption is needed taking into account the high

adsorption of dodine to soil (k<sub>oc</sub> values higher than 20000 mL/g) being considering immobile according to [redacted]'s classification scheme.

The leaching characteristics of dodine in aged soil were studied by [redacted] (2002) in one sandy loam soil, with organic matter content of 2.9%, pH 5.9 of and clay content of 13%. Dodine was applied at a rate of 1.2 mg/kg dry soil and aged under aerobic conditions at soil moisture content equivalent to 48% of water holding capacity, for 78 hours. No significant amounts (< 0.2% of applied) of dodine aged residues were detected in leachates under unsaturated flow conditions. Most of the activity (88-95%) was found to remain in the top of the soil columns consisting mainly of dodine. Little movement of activity down the soil occurred. In the bottom section of the column no significant amounts of activity were found (0.1%). No significant metabolites were observed after leaching. It can be concluded that dodine show low potential to leach into groundwater. Since reliable adsorption coefficients were obtained in the absorption and desorption study of Dodine, the submitted field data are regarded as supplementary information. The results of degradation and other mobility data along with the PEC<sub>GW</sub> simulation results do not indicate any potential for mobility and leaching to groundwater.

**2.8.2 Summary of fate and behaviour in water and sediment [equivalent to section 11.1 of the CLH report template]**

Available environmental fate and ecotoxicology studies have been considered and summarised in the Dodine Monograph (Volume 3, Annex B8 and Annex B9, 2009) and in the renewal of approval dossier (dRAR, Volume 3, Annex B8 and Annex B9).

The key information pertinent to determine the environmental hazard classification for Dodine is presented below. Unless otherwise stated, these studies were conducted in accordance with GLP and the validity criteria of the representative test guideline, if applicable.

**2.8.2.1 Rapid degradability of organic substances**

All the studies considered reliable to characterize both biotic and abiotic degradation of the active substance in water and sediment are used for CLP purposes. They are reported in the following table.

\* data on full mineralization should be reported

#### 2.8.2.1.1 Ready biodegradability

The readily biodegradability of the Dodine was studied by ██████████ (2002) in the DAR of the first approval (Annex I) of the active substance Dodine (DAR, 2009). The results showed that Dodine was not readily biodegradable under the conditions of the modified Sturm test performed.

██████████ (2002).

The ready biodegradability of the active substance Dodine was studied with a test design in line with OECD guideline 301 B “CO<sub>2</sub> Evolution (Modified Sturm Test)”. The study lasts for 28 days according to the OECD guideline. The inoculum used was an activate sludge from municipal sewage treatment plant.

The study was performed in bottles containing 2 litres of suspension. Six bottles were tested with four different treatments: Test item (duplicate), Positive control (single), Inoculum blank (duplicate), Toxicity control (single).

The study met all criteria for acceptability, therefore, this study was considered to be valid.

A ThCO<sub>2</sub> production of 2.30 mg CO<sub>2</sub>/mg was found for the active substance Dodine. Therefore, it was concluded that Dodine is not readily biodegradable under the conditions of the test.

#### 2.8.2.1.2 BOD5/COD

No data available.

### 2.8.2.2 Other convincing scientific evidence

No data available.

#### 2.8.2.2.1 Aquatic simulation tests

##### *Water-sediment studies*

One water-sediment study ([REDACTED] 2004b), was already submitted and accepted during Annex I inclusion of the Dodine (DAR, 2009).

##### [REDACTED] (2004b)

The aerobic degradation of Dodine in two non-contaminated water-sediment systems from Oostvaardersplassen (OVP) and Schoonrewoerdsewiel (SW) in laboratory at 20±2°C in the dark for 84 days. The study has been performed following the guideline SETAC: Procedures for assessing the environmental fate and ecotoxicity of pesticides (Part 1, Section 8.2. Aerobic aquatic degradation), and it was conducted in accordance with GLP. The study was conducted with radiolabelled dodine (radiochemical purity >97.9%) and non-radiolabelled dodine (purity 96.2%). The test substance concentration in the water layer was approximately 100 µg/L. The water used was fully characterized in terms of appearance, hardness, pH, temperature, conductivity and dissolved oxygen.

In the OVP system, mass balances were between 91-107% of AR except on days 0 and 5, when a recovery of 115 and 29% of AR were reported, respectively. However, no trend of decreasing mass balances was observed and, therefore, there were no losses of degradation products could be concluded. In the SW system, mass balances were between 93% and 104% of AR, except at days 8 and 12, when a recovery of 86 and 75%, respectively.

Non-extractable residues in the sediment layer represented a maximum of 58 and 35 % of AR after 1 day in the OVP and the SW system, respectively, and dropped to values of 33% (OVP) and 14% (SW) after 84 days. Mineralisation to CO<sub>2</sub> was the major degradation process (72% OVP, 89% SW after 84 days). In both systems, negligible amounts of volatile organic compounds were formed (≤0.02% of AR).

A polar fraction (M2) was detected in the water phase after extraction and acidification at concentrations higher than 10% of AR (14.5 % AR) in SW system at day 2. In addition, two other polar fractions (M1 and M3) were found at concentrations below 5% of AR. The same fraction (M2) was detected in the water phase of the OVP system, at concentration of 7.8% at day 2 and 12.4 % AR when the analysis is repeated. These fractions could not be identified in this study by TLC.

The metabolites from the polar fraction were not studied at day 5, where high polar fractions, after extraction with methyl acetate were found: 16.2% AR and 37.5% AR for OVP and SW, respectively. However, at this data point the polar fractions after acidification was 5.6 and 6.4% for OVP and SW systems, respectively.

The kinetic calculations presented in the study report are superseded by a re-evaluation (see below [REDACTED], 2021) performed according to recommendations of the FOCUS workgroup on degradation kinetics (2006, 2014).

The study could be considered acceptable. However, several uncertainties have been raised regarding the identity of the metabolites. Two new studies have been conducted to identify the fraction M2 in SW water/sediment system ([REDACTED] 2011 and [REDACTED] 2020).

##### [REDACTED] (2021)

This study has performed a kinetic reanalysis of the experimental data from the two water/sediment systems from the laboratory aerobic degradation study ([REDACTED] 2004b) according to recommendations of the FOCUS workgroup on degradation kinetics (2006, 2014). Persistence DT<sub>50</sub> values for Dodine were calculated to be 0.4 days (0.34 OVP, FOMC kinetics and 0.38 GW, DFOP kinetics), 0.2 days (0.26 OVP, HS kinetics and 0.10 GW, DFOP kinetics) and 3.8 days (5.54 OVP, SFO kinetics and 2.59 GW, SFO kinetics) for the whole system, water compartment and sediment compartment, respectively. DT<sub>90</sub> values were 3.5 days (2.80 OVP, FOMC kinetics and 4.31 GW, DFOP kinetics), 1.5 days (2.06 OVP, HS kinetics and 1.05 GW, DFOP kinetics) and 12.6 days (18.39 OVP, SFO kinetics and 8.60 GW, SFO kinetics) for the whole system, water system and sediment system, respectively.

A brief summary of the modelling endpoints to be used for the risk assessment and persistence endpoints is given in the **Table 2.8.2.2.1-1**.

**Table 2.8.2.2.1-1:** Persistence and modelling endpoints of Dodine in water/sediment systems

| Compartment | System | Persistence endpoints |                  |                  | Modelling Endpoints |                  |                                  |

### ***Aerobic mineralization***

A new study (██████████ 2021) to address data requirement for an investigation of aerobic mineralization in surface water with [<sup>14</sup>C]Dodine was performed for the renewal of approval.

██████████ (2021)

Aerobic mineralisation of [<sup>14</sup>C]Dodine in surface water was investigated under defined laboratory conditions in the dark for 31 days. The study has been performed following the OECD 309 guideline (2004) and in accordance with GLP. A natural water were treated with [<sup>14</sup>C]Dodine at two concentrations (10 and 100 µg a.i./L) and incubated under aerobic conditions at ± 20°C in an aerobic flow-through system with attached traps for the collection of CO<sub>2</sub> and volatile organics, during 31 days. Sterile water was treated with both C-14 labeled test substances at a rate of 100 µg/L and incubated under identical conditions (but without air flow trapping system). System control vessels treated with 14C-benzoic acid showed that the water system used was viable. Dodine dosed samples were analysed immediately after treatment (time 0) and after 1, 2, 5, 10 and 31 days, as well as after 4 hours and 1.17 days of incubation. The water samples were analysed directly by liquid scintillation counter (LSC) and by high-performance liquid chromatography (HPLC). The chloroform phase was concentrated and analysed by HPLC.

The total mean recoveries were 100.3 ± 3.4% AR for the high dose, 102.2 ± 3.3% AR for the low dose and 100.6 ± 4.2% AR for the high dose sterile experiment.

Dodine degraded rapidly in both the high and low dose systems. After two days of incubation, Dodine mean values of 61.5% and 60.4% AR remained in the high dose and low dose system, respectively. Corresponding mean values after 31 days of incubation were 5.4% and 21.4% AR. DT<sub>50</sub> values for [<sup>14</sup>C]guanidine-labelled Dodine in natural surface water were calculated to be 2.3 days for the high dose and low dose, and 200 days for the high dose sterile experiment. DT<sub>90</sub> values were 7.5 and 66.5 days for the high dose and low dose experiment, and 665 days for the high dose sterile experiment. In conclusion, Dodine rapidly degraded in natural surface water system and ultimately mineralized to CO<sub>2</sub>.

One major polar fraction M1 was formed in the high dose and low dose system, indicating a maximum of 74.1% (5 DAT) and 44.8% (5 DAT), respectively. Fraction M1 was identified to consist of three components: 6-{ [amino(imino)methyl]amino} -3-hydroxyhexanoic acid, 6-{ [amino(imino)methyl]amino} hexanoic acid and (2E)-6-{ [amino(imino)methyl]amino} hex-2-enoic acid, each being a result of cleavage and oxidation to carboxylic acid of the Dodine n-dodecyl chain at the level of the C6, eventually combined with dehydrogenation on the remaining chain.

A proposed degradation pathway in surface water under aerobic conditions is described in the following figure.

Figure 2.8.2.2.1-1. Proposed degradation route for Dodine in surface water (study duration 21 days,  $20 \pm 2^\circ \text{C}$ )

### 2.8.2.2.2 Field investigations and monitoring data (if relevant for C&L)

Studies on field soil dissipation of Dodine are not required since laboratory aerobic soil degradation studies confirmed that the degradation of Dodine is rapid. The maximum  $\text{DT}_{50}$  value of 9.5 days and maximum  $\text{DT}_{90}$  value of 31.6 days (at  $20^\circ\text{C}$  and pF2) are below 60 and 200 days, respectively, that would trigger the data requirement for field soil dissipation studies.

One study on soil dissipation of Dodine (KCA 7.1.2.2.1/01) was already submitted and accepted in the DAR of Dodine (2009), and the submitted field data are regarded as supplementary information. The determination of the half-life of Dodine at each test site was based on least squares best fit exponential curves of the results of the analyses after each application. The study results indicate that Dodine has a short half-life ( $\text{DT}_{50}$  and  $\text{DT}_{90}$  range between 6 and 18 days and between 30 and 108 days respectively) and a very low potential for leaching.

No monitoring data for Dodine was available in the DAR (2009) for the Annex I approval of the active substance since it is not applicable and/or not necessary for this active substance. Therefore, no monitoring data of Dodine is submitted for the renewal of the active substance Dodine.

### 2.8.2.2.3 Inherent and enhanced ready biodegradability tests

Please refer to 2.8.2 and to Vol. 3 B.8.2.2.3 (AS) for sediment degradation (water/sediment systems).

#### 2.8.2.2.4 Soil and sediment degradation data

Please refer to 2.8.2 and to Vol. 3 B.8.2.2.3 (AS) for sediment degradation (water/sediment systems).

#### 2.8.2.2.5 Hydrolysis

One study on hydrolysis of Dodine (██████████ 1991) was already submitted and accepted in the DAR of Dodine (2009), prepared in the context of the inclusion of the active substance in Annex I of the Council Directive 91/414/EEC. However, this study has not been included in the Dossier. An additional study (██████████ 2017) has been submitted to evaluate the hydrolysis for the renewal of Dodine according to Regulation (EC) No 1107/2009.

██████████ (2017).

The hydrolytic behaviour of [<sup>14</sup>C]guanidine-labelled Dodine was investigated at pH 4, 7 and 9 in sterile aqueous buffer solutions at 50 °C according to OECD guideline 111 and EPA guideline OCSP 835.2120. It was conducted in accordance with GLP.

The study was performed using radio-labelled [<sup>14</sup>C]guanidine-labelled Dodine over a period of 5 days. A total amount of 19.6 MBq/L was applied to the test system (corresponding to a concentration of 4.1 mg/L) and incubated at 50°C in the dark.

In Tier 1, for all conditions and sampling intervals, the complete mass balances of applied radioactivity (AR) were obtained. The mean recoveries were between 96.4 and 109.1% of applied radioactivity in all sterilized buffer solutions.

The HPLC results indicated less than 10% of hydrolysis in pH ranges 4-9 at 50 °C, which corresponded to a half-life of approximately one year at 25 °C. Based on the results, [<sup>14</sup>C]guanidine-labelled Dodine was found to be hydrolytically stable at acidic (pH 4), neutral (pH 7) and alkaline (pH 9) conditions.

This study can be considered acceptable.

#### 2.8.2.2.6 Photochemical degradation

The photolytic degradation of Dodine in water (██████████ 2004a) was already submitted and accepted in the DAR of Dodine (2009, 2014 additional report). A kinetic reevaluation of this study was performed (██████████ 2021) following the recommendations in the FOCUS degradation kinetic guidance (2006, 2014) and to fulfil the requirement of EFSA Technical report (2019).

██████████ 2004a.

In this study, the photolytic degradation of Dodine in water was studied in buffer pH 7. Natural water or pH 7 buffer were treated with [<sup>14</sup>C]guanidine-labelled Dodine at concentrations of 1.05 and 0.98 mg/L, respectively, and incubated under continuous irradiation with sunlight-simulating light source (Xenon lamp) or under dark conditions, at ±25 °C during 28/30 (buffer pH 7/natural water) days. Only one replicate per treatment was incubated.

Mass balances were all in the range of 93.3-101.5%. In all of the systems, formation of CO<sub>2</sub> was negligible (2.0% of applied) and organic volatile compounds were formed in amounts ≤0.3% of applied.

Results showed that in irradiated buffer pH 7, Dodine degraded slowly (82.1% of AR after 30 days), whereas in irradiated natural water dodine degraded down to 56.9% of AR after 28 days. Dodine was stable in the dark controls of both water types.

At 40°N (draft OECD and OPPTS guidelines), only guanidine might be a relevant metabolite. Guanidine, exceeded 10% of applied radioactivity in the irradiated natural water solution (maximum 42.0% of applied after 14 days in test solution + rinsate) and in the irradiated buffer pH 7 system (max 15% in test solution + rinsate). Guanidine was not encountered in the dark test solutions but it was found in all rinsates of the natural water dark controls (max 13%) and in two rinsates of the pH 7 buffer dark controls (max 7%).

The results showed that direct photolysis is a significant degradation process for dodine in natural aquatic environment.

██████████ (2021).

A recalculation of kinetic parameters was performed for the aquatic photolysis data on Dodine (██████████ 2004a) following the recommendations in the FOCUS guidance (2006, 2014) and to fulfil the requirement of EFSA Technical report (2019). This kinetic evaluation indicates that for irradiated conditions, SFO kinetics provided the best fit for natural water resulting in DT<sub>50</sub> and DT<sub>90</sub> of 11 days and 36.5 days, respectively. The equivalent half-life values in natural summer sunlight days at 40°N for Dodine was found to be 27 and 104 days for DT<sub>50</sub> and DT<sub>90</sub> respectively for natural water.

#### 2.8.2.2.7 Other / Weight of evidence

No additional data available.

### 2.8.3 Summary of fate and behaviour in air

The vapour pressure of Dodine was determined to be  $< 5.49 \times 10^{-6}$  Pa. Based on an evaluation of phototransformation of Dodine in air, Dodine, in the form of dodecylguanidine, has a DT<sub>50</sub> = 1.18 hours following the Atkinson calculations. Due to the low half-life of Dodine in the air (1.18 h) and its very low vapour pressure ( $< 5.49 \times 10^{-6}$  Pa), volatilization Dodine is also expected to be low.

#### 2.8.3.1 Hazardous to the ozone layer

**Table 2.8.3.1-1: Summary table of studies on hazards to the ozone layer**

| Method  | Results | Remarks | Reference |
|---------|---------|---------|-----------|
| No data | -       | -       | -         |

##### 2.8.3.1.1 Short summary and overall relevance of the provided information on hazards to the ozone layer

Based on an evaluation of phototransformation of Dodine in air, Dodine, in the form of dodecylguanidine, has a DT<sub>50</sub> = 1.18 hours calculated with “Estimation Programs Interface (EPI) Suite™ (Version 4.11)” using the model AOPWIN (version 1.92a) and following the Atkinson calculations. Based on these recalculations, total OH rate constant was determined at  $1.08756 \times 10^{-10}$  cm<sup>3</sup> molec. sec., mainly due to reactions with N, S and OH (77%) and hydrogen abstraction (23%). Other mechanisms do not contribute to hydroxyl radical estimations. The total rate of both, OH and ozone constant, is very low. This indicates that any volatilised Dodine will be extremely short-lived in the atmosphere. Therefore, global warming potential, ozone depleting potential, photochemical ozone creation potential and accumulation in the troposphere are all unlikely to occur following use of Dodine according to good agricultural practice.

There are no data provided regarding the hazard of Dodine to the ozone layer, the Ozone Depleting Potential (ODP) of Dodine has not been measured.

##### 2.8.3.1.2 Comparison with the CLP criteria

A substance is considered hazardous to the ozone layer if the available evidence concerning its properties and its predicted or observed environmental fate and behaviour indicate that it may present a danger to the structure and/or the functioning of the stratospheric ozone layer.

Any substances having an ODP of greater than or equal to the lowest ODP (i.e., 0.005) of the substances currently listed in Annex I to Regulation EC No 1005/2009 should be classified as hazardous to the ozone layer (category 1).

Although no specific data have been provided for this hazard, considering the chemical structure and other available information on the physicochemical properties, Dodine is not expected to be hazardous to stratospheric ozone.

##### 2.8.3.1.3 Conclusion on classification and labelling for hazardous to the ozone layer

No classification based on data conclusive but not sufficient for classification is proposed.

## 2.8.4 Summary of monitoring data concerning fate and behaviour of the active substance, metabolites, degradation and reaction products

No data submitted.

## 2.8.5 Definition of the residues in the environment requiring further assessment

For the purpose of risk assessment, the residue definition in all various compartments is limited to the parent compound Dodine. Therefore, the residue risk assessment is defined as Dodine only.

| Compartment(s) | Definition of residue |
|----------------|-----------------------|
| Soil           | Dodine                |
| Groundwater,   | Dodine                |
| Surface water  | Dodine                |
| Sediment       | Dodine                |
| Air            | Dodine                |

## 2.8.6 Summary of exposure calculations and product assessment

### 2.8.6.1 Predicted Environmental Concentrations in soil (PECsoil)

The formulated product Dodine 544 SC is proposed to be applied as fungicide up to 2 times per season to apples/pear, cherry and peach with minimum application intervals of 21 days. The maximum application rates (per application) range between 0.68 kg a.s./ha (apples/pear and cherry) to 0.9 kg a.s./ha (peach), equivalent to 1.25 L product/ha and 1.65 L product/ha, respectively.

Initial predicted concentrations in soil ( $PEC_{s, act}$ ) values for the active substance dodine were calculated with ESCAPE 2.0 model assuming worst case conditions for application and crop scenarios : 2 applications at 0.9 kg a.s./ha in peach with a minimum interval of 21 days between applications. Plant interception was set to 50% for 1<sup>st</sup> application and 2<sup>nd</sup> application, respectively. A  $DT_{50}$  value of 17 days (the longest laboratory persistence  $DT_{50}$  at 20°C) from an aerobic laboratory soil degradation study was used for Dodine. As Dodine degrades rapidly in soil with no potential for accumulation, calculation of plateau and accumulation concentrations are not required. Refer to Vol. 3 CP B8 Point B.8.2 for further details.

The calculation was performed assuming up to 2 applications of Dodine 544 SC to pome/pears, cherry and peach, where the maximum  $PEC_s$  after the last application was calculated to be 0.646 mg/kg, 0.514 mg/kg and 0.730 mg/kg, respectively.

### 2.8.6.2 Predicted Environmental Concentrations in groundwater (PECgw)

$PEC_{GW}$  values for Dodine were below the trigger value of < 0.1 µg/L for all modelled scenarios and crops following modelling with FOCUS PEARL 4.4.4, FOCUS PELMO 5.5.3 and FOCUS MACRO 5.5.4. The PEC in groundwater was assessed calculating the 80<sup>th</sup> percentile concentrations of 26 years for peach only which is the worst-case scenario and covers all the representative uses (apples/pear, cherry and peach).

All calculated  $PEC_{gw}$  values for dodine were below the trigger value of 0.1 µg/L. Therefore, it is concluded that an unacceptable risk to groundwater after application of Dodine 544 according to the GAP is not expected.

### 2.8.6.3 Predicted Environmental Concentrations in soil (PECsw)

A FOCUS SW calculation for the product Dodine 544 SC was performed to predict the concentration of residues in surface water ( $PEC_{SW}$ ) and aquatic sediment ( $PEC_{SED}$ ).  $PEC_{SW}$  and  $PEC_{SED}$  values for FOCUS evaluation Steps 1 and 2 were calculated using the modelling software STEPS 1-2 (version 3.2). Within the scope of evaluation Steps 3 and 4, for every main entry route different software was used as recommended, i.e. FOCUS SWASH 5.3, Drift calculator 1.1 (spray drift), MACRO 5.5.4 (drainage) and PRZM 4.3.1 (runoff). Based on the different pesticide

inputs calculated, TOXSWA 5.5.3 was used to simulate the fate of pesticide entries in typical surface water bodies and finally to calculate maximum as well as actual and time weighted average concentrations in water layer and sediment for different dates or periods. Step 4 calculations were performed using the model-software Surface Water Assessment eNabler (SWAN) v 5.0.1 by taking mitigation options into account such as no-spray buffer zones (reduction of drift entries) and vegetated buffer zones or filter strips.

Based on predicted environmental concentrations in surface water for the parent Dodine, it was necessary to consider higher tier modelling approaches for all uses (FOCUS Step 3 and 4). For Dodine, a Tier 1-RAC of 0.18 µg/L was used for the risk assessment. Moreover, a ETO-RAC of 0.4 µg/L and a ERO-RAC of 2.5 µg/L derived from a mesocosm study (Hoomen, 2021b) have been proposed for refinement purposes Please refer to Vol. 3 CP B.9 Point B.9.4 for further details.

#### 2.8.6.4 Predicted Environmental Concentrations in air (PECair)

The chemical properties that most affect volatilisation are vapour pressure and Henry's law constant. Dodine has a low volatility (vapour pressure  $< 5.49 \times 10^{-6}$  Pa at 50°C) and a Henry's law constant lower than  $1.69 \times 10^{-6}$  Pa m<sup>3</sup>/mol, suggesting little potential for volatilisation in the environment.

Based on an evaluation of phototransformation of Dodine in air, Dodine, in the form of dodecylguanidine, has a DT<sub>50</sub> = 1.18 hours following the Atkinson calculations.

Due to the low volatilization potential and fast degradation of dodine in air, dodine is not expected to be subject of atmospheric short- or long-range transport. Therefore, model calculations of off-site deposition (PEC) originating from volatilisation are not required. Likewise, calculations of concentrations from airborne transport are not required.

#### 2.8.6.5 Predicted Environmental Concentrations for other routes of exposure

Atmospheric exposure resulting from other routes of exposure such as deposition of dust by drift during sowing, amenity use or indirect exposure of surface water via a sewage treatment plant (STP) after application of a plant protection product in storage rooms is not anticipated following application of the Dodine 544 SC formulation to agricultural crops as proposed. Therefore, further information is not required.

### 2.9 EFFECTS ON NON-TARGET SPECIES

#### 2.9.1 Summary of effects on birds and other terrestrial vertebrates

##### 2.9.1.1 Summary of effects on birds

Studies on the acute oral, short-term dietary and reproductive toxicity of Dodine technical to birds were already submitted for the first EU evaluation for the Annex I inclusion of the active substance. No study assessing the effects of the representative product to birds has been conducted as it is possible to extrapolate from the data available on the active substance. Although no new study relevant to address the core data requirements for either the active substance or the formulated product has been conducted for the purpose of renewal of the approval of Dodine, two new higher-tier field studies investigating the effects to blue tits and great tits following Syllit 400 SC applications under realistic use conditions are available. However, these studies were considered as supporting information by the RMS since the application of Syllit SC 400 (2x250 g a.s./ha/m crown height in approx. 1-4 weeks interval) was not a realistic worst case compared to the Dodine SC 544 as proposed in the GAP (2x680 g a.s./ha and 2x900 g a.s./ha, 21 days interval).

Considering the available, complete data set, the geometric mean of the LD<sub>50</sub> on mallard duck and the LD<sub>50</sub> on bobwhite quail as derived from the available short-term dietary studies, i.e., 548.1 mg a.s./kg bw, is used in the regulatory acute risk assessment and the lowest NOEL of 20 mg a.s./kg bw/d for mallard duck is used in the regulatory long-term/reproductive risk assessment for birds.

A summary of the endpoints derived from the bird studies with Dodine is presented in Table 2.9.1.1 1. The values in bold were used for risk assessment.

**Table 2.9.1.1-1 Effects of Dodine to birds**

| Test substance  | Test species  | Exposure System                        | Endpoint  | Reference  | Endpoint used in the risk assessment                               |

a.s.  
1 active substance  
An LD<sub>50</sub> of 857 mg a.s./kg bw is reported in EFSA Journal 2015;13(8):4209; however, this endpoint is no longer considered reliable for use in the risk assessment, the NOEL should be further considered from the acute oral toxicity. Further details are provided in the summary of the study (Vol. 3 CA B.9.1.1.1/02).

The risk assessment for effects on birds is carried out according to the Guidance Document on Risk Assessment for Birds and Mammals on request from EFSA (EFSA Journal 2009; 7(12): 1438). The acute and long-term risks of Dodine formulated as Dodine 544 SC to birds were assessed from toxicity exposure ratios between toxicity endpoints, derived from studies with Dodine technical and estimated exposure based on the maximum residues occurring on food items following applications according to the proposed use pattern.

#### *Acute dietary risk assessment*

The geometric mean of the LD<sub>50</sub> on mallard duck and the LD<sub>50</sub> on bobwhite quail as derived from the available short-term dietary studies, i.e., 548.1 mg a.s./kg bw, is used in the regulatory acute risk assessment for birds. All TER<sub>A</sub> values for Dodine calculated for the relevant exposure scenarios exceed the trigger of 10 at screening step, indicating no potential acute risk for birds following the representative uses of Dodine 544 SC in apples/pear, cherry and peach.

#### *Long-term dietary risk assessment*

The lowest NOEL of 20 mg a.s./kg bw/d for mallard duck is used in the regulatory long-term/reproductive risk assessment for birds. All TER<sub>LT</sub> values for Dodine calculated for the relevant exposure scenarios exceed the trigger of 5 at Tier 1 except for small granivorous birds feeding in treated apples/pear and peach fields and small insectivorous birds feeding in treated apples/pear, cherry and peach fields. For these two types of diet guild, a higher tier risk assessment is performed by considering focal species, i.e., a real species that actually occur in the crop when the pesticide is being used, and their ecological properties (i.e. PT: Proportion of diet obtained in the treated area), by refining the residue decline (DT<sub>50</sub>) in potential food items of the identified focal species and by incorporating in the exposure estimation the interception by the crop.

Taking into account the above refinements high risk is still identified for small insectivorous birds for the following scenarios:

- All EU Zones: Long-term risk for small insectivorous birds, application on spring summer, for the intended use on peach ( $2 \times 0.9$  kg a.s./ha, 21-day interval)
- Southern Zone and Northern Zone: Long-term risk for small insectivorous birds, application on spring summer, for the intended uses on Apples/pear and cherry ( $2 \times 0.68$  kg a.s./ha, 21-day interval).

The risk for granivorous birds herein has been addressed.

Consequently, low risk has been identified for the intended uses on Apples/Pear and cherry ( $2 \times 0.68$  kg a.s./ha, 21-day interval) in the Central Zone.

#### *Drinking water risk assessment*

Based on the ratios of the effective application rate to the relevant toxicity endpoints, an acceptable risk is demonstrated for birds due to exposure to Dodine via contaminated drinking water in puddles (puddle scenario). Further, considering the representative uses of Dodine 544 SC in orchards, no risk to birds is expected via exposure to contaminated drinking water in leaf whorls (leaf scenario).

#### *Secondary poisoning*

The log P<sub>ow</sub> of Dodine does not exceed the trigger value of 3; thus, a risk assessment of secondary poisoning for earthworm- and fish-eating birds is not required.

### 2.9.1.2 Summary of effects on mammals

Studies considering the toxicity of dodine and the representative formulation to mammals were assessed for their validity to current and relevant guidelines. A more detailed summary and evaluation by the RMS are provided in Vol 3 CA B6, section 6 and Vol 3 CP B6, section 6.

#### 2.9.1.2.1 Acute oral toxicity to mammals

Details of the acute oral studies on mammals are summarised in Volume 3 CA B6, section 6.1. A study with Dodine 544 SC on the acute oral toxicity in rat has been conducted and summarised in Volume 3 CP, section B.6.1.1.

Studies on the acute oral toxicity of Dodine technical to rats and mice were already submitted for the first EU evaluation for the Annex I inclusion of the active substance. The rat LD<sub>50</sub> was calculated to be 851 mg a.s./kg bw while the mouse LD<sub>50</sub> was calculated to be 1354 mg a.s./kg bw. For risk assessment purposes, the geometric mean LD<sub>50</sub> of these endpoints, i.e., 1073 mg a.s./kg bw, was further considered. In addition to the already EU peer reviewed studies, an acute oral toxicity study with the formulation Dodine 544 SC is available which is newly submitted for the purpose of renewal of the EU approval of Dodine. The LD<sub>50</sub> of Dodine 544 SC has been calculated to be > 300 mg/kg bw and < 2000 mg/kg bw by oral route in the rat. In accordance with the OECD guideline 423, the LD<sub>50</sub> cut-off of Dodine 544 SC may be considered as 500 mg/kg bw (corresponding to 267.9 mg a.s./kg bw) by oral route in the rat. A summary of the relevant acute endpoints that are most appropriate for ecological risk assessment is provided in **Table 9.1.2.1-1**.

**Table 2.9.1.2.1-1 Summary of acute effects of Dodine to terrestrial mammals**

| Test substance | Test species | Exposure System | Endpoint  | Reference                                | Endpoint used in the risk assessment                |
|----------------|--------------|-----------------|---|--|---|
| Dodine         | Rat          | Oral Acute      | LD <sub>50</sub> = 851 mg a.s./kg bw                                    | █ (1999)<br>Please refer to KCA 5.2.1/01 | <b>Geomean LD<sub>50</sub> = 1073 mg a.s./kg bw</b> |
| Dodine         | Mouse        | Oral Acute      | LD <sub>50</sub> = 1354 mg a.s./kg bw                                   | █ (2008)<br>Please refer to KCA 5.2.1/02 |   |
| Dodine 544 SC  | Rat          | Oral Acute      | LD <sub>50</sub> = 500 mg f.p./kg bw = 267.9 mg a.s./kg bw <sup>a</sup> | █ (2011)<br>Please refer to KCP 7.1.1/01 | -   |

The lower LD<sub>50</sub> of 267.9 mg a.s./kg bw derived from the formulation study compared to the LD<sub>50</sub> endpoints derived from the studies conducted with the active substance does not imply that Dodine is more acutely toxic to rats when formulated to Dodine 544 SC. This difference can be explained by the different methods used for testing in each study. For Dodine 544 SC, the OECD testing guideline 423 (toxic class method) was used. To reduce the number of vertebrates tested, a minimum number of animals was used following a step wise approach. As a consequence, no accurate LD<sub>50</sub> but a range (300 - 2000 mg/kg bw) has been set; according to the guideline a cut-off value of 500 mg/kg has been derived based on the use of 9 female animals (which are the most sensitive gender). If more animals (with males included) were used, the real LD<sub>50</sub> could have been found higher somewhere between 500 and 2000 mg/kg. For Dodine technical, the OECD testing guideline 401 was used. Thirty animals (5/5 male/female animals at 3 dose levels) were tested allowing to calculate an exact LD<sub>50</sub> of 851 mg/kg (for males and females combined). The LD<sub>50</sub> for females only ranged between 450 and 761 mg/kg. Finally, it can be concluded that the results obtained with both Dodine technical and Dodine 544 SC are of the same order of magnitude and that Dodine 544 SC is not expected to be more toxic than Dodine technical.

In line with the recommendations given in EFSA (2009)<sup>5</sup>, the geometric mean of the two LD<sub>50</sub>s on acute oral toxicity of Dodine technical to rats (LD<sub>50</sub> = 851 mg/kg bw) and mice (LD<sub>50</sub> = 1354 mg/kg bw), i.e., 1073 mg a.s./kg bw, is further used in the acute risk assessment for wild mammals. This approach was already proposed and agreed during the first EU peer review of Dodine. According to EFSA (2009), the geometric mean should be used for the acute assessment, except when the endpoint for the most sensitive species is more than a factor of 10 below the geometric mean of all the tested species. Where this is the case, the most sensitive species will be used for the risk assessment

<sup>5</sup> European Food Safety Authority; Guidance Document on Risk Assessment for Birds & Mammals on request from EFSA. EFSA Journal 2009; 7(12):1438.

but generally without any assessment factor (unless there are specific reasons to believe that this is not appropriate). Since the lowest LD<sub>50</sub> of 851 mg/kg bw is not more than a factor of 10 below the geometric mean of 1073 mg/kg bw, the later endpoint is used for the acute assessment.

In terms of studies comparability, the acute oral toxicity study with rats (█████ 1999) followed the EPA OPPTS Guideline 870.1100 (1998) and the OECD Guideline 401 (1987) while the acute oral toxicity study with mice (█████ 2008) followed the EPA Guideline 870.1000 and the OECD Guidance 425. In the former study the test material was diluted in 0.5% methylcellulose while in the later study the test material was diluted in distilled water before oral administration via gavage; both vehicles are assumed to be of low toxicity. Despite any methodological differences between the two studies (i.e., different number of animals and use of males/females or only females), endpoint setting in each study primarily depended on the dose selection and the species sensitivity. The result of rats being more sensitive than mice was also confirmed in the repeated dose studies – then it is not only for mortality but for all effects.

#### 2.9.1.2.2 Long-term toxicity to mammals

Details, full description and RMS assessment of the toxicity studies used in this risk assessment can be found in Volume 3 CA Section B.6 and Volume 3 CA Section B.9, Point 9.1.2.2. An overview table is presented below.

Considering the available complete data set, the NOAEL of 26 mg/kg bw/d is proposed for use in the Tier 1 long-term risk assessment.

All data indicate that the critical effects of Dodine are decreased food consumption accompanied by a reduction in the body weight. Therefore, results should be interpreted with some caution. Dodine is a clear irritant and it is very plausible that irritancy in the stomach have contribute to the observed response. No effects on fertility or reproduction were observed and no other developmental effects than reduction in pup body weight were reported.

Considering all data, the lowest NOAEL for derivation of the chronic mammalian endpoint for Dodine is the lowest value seen in dogs of 10 mg/kg bw/day, in a 90-day study (█████ 2005) and in a one-year study (█████ 1996). However, RMS agrees with the applicant that the ecotoxicologically relevant NOAEL should be set to 26 mg/kg bw/day, based on the following findings:

- In the 90-d oral toxicity study with dogs (█████ 2005), the reduction in *body weights seen at 20 mg/kg bw/d was non- statistically significant, being the mean body weights of the female dogs at this dose in the normal range of healthy beagle females. Therefore, a NOEAEL of 20 mg/kg bw/d was proposed by RMS (ecotoxicology).*
- In the one year (52 weeks) oral toxicity study with dogs (█████ 1996) a *NOEAEL of 20 mg/kg bw/d was proposed by RMS (ecotoxicology), since severe effects on food consumption and body weight that require supplemental feeding of animals to prevent mortality were considered to be incidental cases and, therefore, of low population relevance. No other relevant effects were seen.*
- In the chronic oral toxicity study with rats (█████ 1998), the NOAEL for lifetime exposure of rats to Dodine was 400 ppm, approximately 20 and 26 mg/kg/d in males and females, respectively, based on a decrease in bw (up to 10% in males and to 15% in females) and food consumption.
- In the mouse study (█████ 1998), the NOAEL was set to 200 ppm (29 and 38 mg/kg bw per day in males and females, respectively) based on the same effects, decreased body weight gains and food consumption.

*The above studies support the selected chronic endpoint of 26 mg/kg bw/day, derived from two generation study with rats (█████ 1996) as ecotoxicologically relevant based on the following findings: statistically significant reduction in bw of F1 adults (up to -15.5%) and F1 and F2 pups (up to 17.7%) at 800 ppm.*

Please, refer to **Table 9.1.2.2-1** for further details on the ecotoxicological relevance assessment of the mammalian chronic endpoints.

| <b>Neurotoxicity</b>   |   |   |  |  |                  |  |           |
| Dodine is not similar or related to active substances capable of inducing neurotoxicity, or active substances which induce specific indications of potential neurotoxicity, neurological signs or neuropathological lesions. In addition, no indications of neurotoxicity have been seen in the repeated dose studies. |   |   |  |  |                  |  |           |

\* According to the draft GD on B&M that is not applicable to the renewal of dodine, it is considered that the use of the BMDL10 for bodyweight endpoints is ecologically relevant.

### 2.9.1.3 Summary of effects on other terrestrial vertebrates

To address potential endocrine disrupting properties of dodine, an Amphibian Metamorphosis Assay according to OECD 231 was conducted. Lethal and sublethal effects as well as effects on the normal function of the hypothalamic-pituitary-thyroid (HPT) axis on tadpoles of *Xenopus laevis*, caused by the test item Dodine technical, were investigated. The tadpoles were exposed in a flow-through test during a period of 21 days to the nominal concentrations of 2.0, 10.0 and 50.0 µg/L (mean measured: 2.4, 5.8 and 29 µg/L), and to a control group consisting of aqueous test media and a solvent control group, containing the solvent dimethyl sulfoxide (DMSO). The study fulfilled the performance criteria reported in the OECD 231 guideline, except with the related to the variability of measured test concentrations over time, as CV was slightly above the limit. Considering the observed behaviour of the test item in test medium, the outcome was considered acceptable. No significant differences on the development stage were observed. A reduction of wet weight (22%) and of the SVL (11%) were observed at the middle test concentration (5.8 µg/L) at day 7, and a slight increase of both parameters at the lowest concentration at the end of the assay were found (2.4 µg/L). These effects on wet weight and SVL were considered no dose-related. The normalized Hind Limb Length (by SVL) of larvae was significantly reduced at day 7 at the lowest concentration, and in all treatments at the end of the study for larvae at NF ≤ 60 (reduction 10-14%), but not for tadpoles above stage NF 60. However, as no acceleration of HLL development was found, the effects observed on this parameter were not considered thyroid-related. Normal morphological development of tadpoles was reported, then, no asynchronous development was identified. Histopathological results could not be assessed by RMS (images not available, **DATA GAP**). In addition, RMS has **concerns** about the results relevance, as the selected doses did not cover the MTC (as recommended in the ED guidance and OECD 231) and could be too low to elicit any possible ED mediated effect. The results of the study should be used in the risk assessment with caution, as it only showed the ED effects up to the highest concentration tested.

#### 2.9.1.3.1 Higher-tier effect data on mammals

In addition to the Tier 1 studies submitted to address the core data requirements for the active substance, higher-tier effect studies conducted with formulated Dodine are also presented in Volume 3 CP Point 9.1.2.3 (██████████ 2009; ██████████ 2018). They are used in a weight of evidence consideration by the applicant, **However, due to the lack of statistical information regarding the statistical power of the the study or MDDs in order to demonstrate that the test is able to detect effects on acute or reproductive parameters, RMS has concluded that the results of higher-tier effect studies (██████████ 2009; ██████████ 2018) should not be used in the risk assessment of mammals pending on the submission of a re-evaluation of the statistical power of the field studies (data gap).**

██████████ (2009), which was already submitted for the first Annex I inclusion of Dodine, investigated the potential long-term effects of Dodine formulated as Syllit 400 SC on free ranging, naturally occurred small herbivorous mammals (i.e., common vole). The field study was conducted in grassland as surrogate for orchards in Germany to show that the use of the active substance has no negative acute and long-term impact on common vole populations. In addition, a new study (██████████ 2018) was conducted in grassland in Germany to investigate potential long-term effects of formulated Dodine as Syllit 544 SC on voles inhabiting semi-field enclosures. The later study serves as an addition to the previously conducted field study. Both studies were conducted in grassland as this type of habitat is comparable to ground vegetation in orchards.

In the first study by ██████████ (2009), three study plots were treated with Syllit 400 SC and three study plots were used as control fields, where no application took place. Four applications of Syllit 400 SC were performed on each of the three treatment plots. The treatment was performed in two blocks of two applications in a 6–7-day interval, i.e., 1<sup>st</sup> application: 9 July 2008, 2<sup>nd</sup> application: 16 July 2008, 3<sup>rd</sup> application: 20–21 August 2008, 4<sup>th</sup> application: 27 August 2008. The application rate used in treatment block 1 ranged from 853.98 to 953.64 g a.s./ha. A reduced application rate ranged from 452.11 to 475.41 g a.s./ha (simulating 50% interception in orchards) was used in the second block. “Capture-Mark-Recapture” methodology was used to monitor common vole populations. Live trapping was carried out for approximately 15 weeks. One treatment and one control plot were set up in pairs on the same grassland field with a minimum distance of 100 m. Ugglan multiple-capture traps were used to live-trap voles, which were marked with passive integrated transponders and released at the site of capture. Following the initial trapping session (29 June 2008), the first treatment block took place followed by four weekly trapping sessions before treatment block 2. Six further weekly trapping sessions were carried out after the last Syllit 400 SC application. The numbers of voles captured and/or recaptured during each of the trapping sessions were used to calculate Minimum Numbers Alive (MNA). MNA values were then used to compare vole population dynamics between voles exposed to the test item on the treatment plots and those on the control plots. The persistence of voles in the study plots and information on age structure could also be derived from the live trapping data.

Abundances of common voles were generally low on all plots at begin of the study, increased during the study and then decreasing towards the end of the study on all plots. The stepwise comparison of populations on treatment and control plots for each trapping session after the first treatment block showed no significant difference in population development of common voles between control and treatment plots. The common vole populations on all treatment and control plots showed analogous age structures during the study period. There was general trend of decreasing proportions of adult common voles and increasing proportions of subadults towards the later trapping sessions on all plots. The population persistence in the study plots varied greatly among the individuals on all plots. However, there was no significant difference between the mean numbers of persisting days in neither male nor female common voles between control and treatment plots. A common feature of all populations was that the cohort of individuals captured only once made up more than 50% of all marked common voles. Overall, there was no long-term effect of Syllit 400 SC applications on common vole populations in grassland detected. No statistically significant differences were found in population development and persistence of common voles known to have been exposed to the test item.

In the second study by [REDACTED] (2018), semi-field enclosures covered with meadow-like vegetation were used compared to the open system field effect study by [REDACTED] (2009). A controlled number of individuals were used as founder population, which were exposed to the treatment, and the following reproductive activity and population development was monitored on individual level. No migration or predation occurred on the study plots during the trapping period. Voles were placed in the enclosures in early spring 2017. Five enclosures were treated with Syllit 544 SC and five untreated enclosures served as controls. The first application of the test item was conducted on 20 April 2017 at a nominal application rate of 900 g a.s./ha, shortly after the release of the founding common vole populations per enclosure. The second application was carried out seven days after the first application (27 April 2017) and the third application was conducted 21 days after the first application (11 May 2017). This study design ensured that all voles in the treatment enclosures were exposed via diet (and other routes) to the test item. Live trapping was conducted using the Capture-Mark-Recapture (CMR) design with 'Ugglan' multiple capture live traps, allowing identification of individually marked animals upon recapture. The live trapping campaign was carried out between 24 April 2017 and 12 June 2017 to assess population dynamics of common voles in the treated enclosures compared to the control enclosures. Focus was on investigating development of vole densities (i.e., abundance values), Minimum Number Alive (MNA), recapture rate, longevity and survival rates of individual marked voles based on equal founder population in treated and untreated enclosures as well as further parameters such as body weight, reproductive status, sex and age.

The results of trapping success were in the same range for control and treatment. The Minimum Number Alive (MNA) increased over time for control and treatment with approximately the same slope and were slightly higher in the treatment enclosures. The MNAs in the single trapping sessions of the enclosures were similar. The proportion of reproductive active individuals fluctuated in both control and treatment, and again in the same range. The number of juveniles, the reproductive success of the founder females and the longevity of the founders was nearly identical. Exposure to the voles in treatment enclosures was verified (all diet treated). Overall, the comparison of various population parameters derived from live trapping data and related to reproduction revealed no negative effects on common voles that could be attributed to the test item. Therefore, it can be concluded that within this study no acute or long-term effects of the fungicide Dodine applied as Syllit 544 SC on common voles were detected. It is noted that the study by [REDACTED] (2018) serves as an addition to the previously conducted field effect study in which free-ranging voles were exposed to the same test item later in the season (i.e., early summer).

## 2.9.2 Summary of effects on aquatic organisms [section 11.5 of the CLH report]

The effects of Dodine (either technical or formulated) to aquatic organisms have been investigated in various Tier 1 and higher tier studies conducted to provide reliable endpoints regarding the acute and long-term/chronic toxicity to fish and aquatic invertebrates, the potential growth inhibition of green algae and aquatic macrophytes, the long-term toxicity to sediment dwellers following water borne exposure and the effects on freshwater ecosystems under field conditions. Most of the available studies were already submitted for the first EU evaluation for the Annex I inclusion of the active substance. New studies submitted for the purpose of the renewal of approval of the active substance include two studies on the acute toxicity of Dodine technical to fish (*Cyprinus carpio*) and additional aquatic invertebrates (*Mysidopsis bahia*), respectively, two studies on the acute toxicity of Dodine 400 SC and Dodine 544 SC on aquatic invertebrates (*Daphnia magna*), three studies assessing the effects of Dodine technical, Dodine 400 SC and Dodine 544 SC on algal growth inhibition, a study on the growth inhibition of Dodine technical to aquatic macrophytes (*Lemna gibba*) and an outdoor mesocosm study in artificial freshwater ponds conducted with the current representative product, i.e., Dodine 544 SC. In addition to the later mesocosm study, a further mesocosm, already EU peer reviewed study is available which has statistically been re-evaluated for the purpose of the renewal of the approval of Dodine. Considering the available, complete data set, the assessment of potential effects and risks to aquatic organisms is based on the RAC values presented below.

**Table 2.9.2-1 Acute and long-term RAC values used in the aquatic risk assessment**

| Taxonomic group/exposure regime | Tier I RAC [ $\mu\text{g a.s./L}$ ] | Higher-tier RAC [ $\mu\text{g a.s./L}$ ]    |
|---------------------------------|-------------------------------------|---|
| Fish/acute                      | 3.12                                | Geomean RAC = 12.55                         |
| Fish/long-term                  | 20                                  | -   |
| Aquatic invertebrates/acute     | 0.18                                | ETO-RAC = 0.4<br>ERO-RAC = 2.5 <sup>1</sup> |
| Aquatic invertebrates/long-term | 0.44                                |   |
| Algae                           | 0.55                                |   |
| Aquatic macrophytes             | 6.3                                 |   |
| Sediment dwellers/long-term     | 88.3                                | -   |

**2.9.2.1 Bioaccumulation [equivalent to section 11.4 of the CLH report template]**

Table 69: Summary of relevant information on bioaccumulation

| Method   | Species | Results  | Key or Supportive study            | Remarks                  | Reference          |
|--|---------|--|------------------------------------|--------------------------|--------------------|
| Partition coefficient n-octanol/water<br><br>EEC A8, OECD 107 (Shake-flask method) | -       | log P <sub>ow</sub> value for Dodine = 0.96 (at pH range 4.6 – 9.3)  | The study is considered acceptable | Dodine purity 99.2% w/w  | ██████████ (1999c) |
| Partition coefficient n-octanol/water<br><br>Estimated by calculation              | -       | Based on Dodine solubilities at 20°C in water and in n-octanol<br><br>log Pow: 1.28. (pH: 4.9)<br>log Pow: 1.25. (pH: 6.9)<br>log Pow: 1.32. (pH: 9.1) | The study is considered acceptable | Estimated by calculation | ██████████ 2006    |

**2.9.2.1.1 Estimated bioaccumulation**

No relevant, see 2.9.2.1.

**2.9.2.1.2 Measured partition coefficient and bioaccumulation test data**

The log P<sub>ow</sub> value for Dodine is between 1.25 – 1.32 at 20°C, at pH range 4.9 – 9.1

The pH value has no impact on the octanol/water partition for Dodine. In line with Annex I, Section 4.1.2.8.1 of the CLP Regulation, these log P<sub>ow</sub> values are less than the CLP cut-off criteria of 4, indicating Dodine does not show potential to bioaccumulate.

### 2.9.2.2 Acute aquatic hazard [equivalent to section 11.5 of the CLH report template]

The risk assessment for aquatic organisms was carried out according to the Guidance on tiered risk assessment for plant protection products for aquatic organisms in edge-of-field surface waters. EFSA panel on plant protection products and their residues (PPR). European Food Safety Authority (EFSA), Parma, Italy. EFSA Journal 2013;11(7):3290. The relevant information of acute aquatic toxicity is summarized below (Table 2.9.2.2-1).

Following the recommendations of the EFSA 2015 and 2019 (supporting publication 2015:EN-924. 62 pp. and EFSA Supporting publication 2019:EN-1673) on how to express the endpoints from tier 1 studies, the endpoints from those static/semi-static tests where the measured concentrations of the test substance were not satisfactorily maintained within  $\pm 20\%$  of the nominal throughout the test, were re-calculated based on the geometric mean measured concentrations. For flow-through studies only, the arithmetic mean were used to calculate the mean measured concentration when test concentrations were not satisfactory maintained.

**Table 2.9.2.2-1 Summary of relevant information on acute aquatic toxicity**

| Method   | Species                      | Test material        | Results                                 | Key or Supportive study                               | Remarks                | Reference  |

### 2.9.2.2.1 Acute (short-term) toxicity to fish

Five studies with dodine and one with the formulated product Dodine 400 SC were performed to assess their acute toxicity to fish. These studies (technical and formulated) were already submitted for the first EU evaluation for the Annex I inclusion of the active substance. Nevertheless, a new study assessing the acute toxicity of Dodine technical to *Cyprinus carpio* under flow-through conditions (██████████ 2006; KCA 8.2.1/02) is available. This study provides the lowest LC<sub>50</sub> (and thus RAC) for acute toxicity of Dodine to fish, i.e., 312 µg a.s./L. All of these studies have been evaluated for the current application for the renewal and are considered acceptable by RMS. The relevant information of acute aquatic toxicity for fish is summarized below (Table 2.9.2.2.1-1).

No study was performed with the formulation Dodine 544 SC since it is possible to extrapolate data from the available study performed with the similar formulation Dodine 400 SC. The formulations Dodine 400 SC and Dodine 544 SC are fungicides based on the same active substance. The contents of the active substance are rather similar, i.e., Dodine 400 SC contains 41.49% (w/w) while Dodine 544 SC contains 55.66% (w/w) Dodine. In addition to the active substance, the two formulations share comparable compositions with regard to the type of co-formulants and their contents. Any compositional differences are not assumed to enhance the ecotoxicity profile of Dodine 544 SC compared to Dodine 400 C. Therefore, it is possible to use toxicity studies performed with Dodine 400 SC to extrapolate toxicity values to Dodine 544 SC when expressed as active substance equivalents. Please refer to Confidential Information for further details.

In addition, bridging studies under similar conditions with both Dodine 400 SC and Dodine 544 SC with aquatic non-vertebrate species (i.e., *Daphnia magna* and *Desmodesmus subspicatus*) were performed (██████████ 2013a-d). The results of these studies confirm the equivalence of toxicity expected based on similar composition. Therefore, the formulation Dodine 400 SC could be considered as a surrogate for assessing the toxicity of Dodine 544 SC for aquatic organisms.

It is further noted that according to Regulation (EU) No 284/2013 and EFSA (2013)<sup>6</sup>, in principle, acute exposure tests should be carried out on one species from each of the taxonomic groups fish, aquatic invertebrates, algae and/or macrophytes (in case the active substance is an herbicide or exhibits herbicidal activity); however, where the available information for the active substance permits the conclusion that one of these groups is clearly more sensitive (factor of 10 difference), only a test using a species of the relevant group needs to be performed with the formulated product. Based on the acute toxicity of Tier 1 taxonomic groups (i.e., 96-h LC<sub>50</sub> 312 µg/L for fish, 48-h EC<sub>50</sub> 18 µg/L for aquatic invertebrates, 72-h ErC<sub>50</sub> 5.5 µg/L for algae and 7-d ErC<sub>50</sub> 63 µg/L for aquatic macrophytes), the difference in sensitivity between fish and the most sensitive species, i.e., aquatic invertebrates and algae, is more than a factor of 10, i.e., 17 and 57, respectively. Thus, fish acute toxicity testing with the formulation is not necessary.

Considering that several studies on the acute toxicity to fish are available assessing the same effect parameter (i.e., mortality) within the same exposure duration (i.e., 96 hours) by following identical testing guidelines, it is proposed to calculate the geomean LC<sub>50</sub> of all available endpoints for further use in the risk assessment. Since the endpoint derived from the available formulation study with Dodine 400 SC is within the range of calculated endpoints from the studies with Dodine technical, the formulation endpoint expressed as active substance equivalents is included in geomean LC<sub>50</sub> calculation. It is noted that by excluding the formulation study the geomean LC<sub>50</sub> will be slightly affected, i.e., it will be decreased from 1255 to 1141 µg a.s./L. In any case the geomean RAC (12.55 or 11.41 µg a.s./L) for acute toxicity to fish would be lower than the lowest LC<sub>50</sub> for the most sensitive species, i.e., 312 µg/L, thus the geomean approach is applicable according to EFSA (2013)<sup>1</sup>.

**Table 2.9.2.2.1-1. Summary of acute toxicity of dodine to fish and derivation of RAC for the risk assessment**

<sup>6</sup> EFSA PPR Panel (EFSA Panel on Plant Protection Products and their Residues), 2013. Guidance on tiered risk assessment for plant protection products for aquatic organisms in edge-of-field surface waters. EFSA Journal 2013;11(7):3290, 268 pp. doi:10.2903/j.efsa.2013.3290.

| Endpoint   | Test substance | Toxicity                   | Value selected              | Geomean                     |

| <i>Cyprinus carpio</i> – 96-h LC <sub>50</sub>       | Dodine 400 SC  | 1360 µg a.s./L             |                             |                             |

a Pending on the submission of the statistical robustness by the applicant.

b Geometric mean calculation is based on the results from all available acute toxicity studies with fish including the formulation study. Preliminary endpoint, pending on the submission of the statistical robustness of some LC<sub>50</sub> by the applicant.

#### 2.9.2.2.2 Acute (short-term) toxicity to aquatic invertebrates

Five studies with dodine and three with the formulated products Dodine 400 SC and Dodine 544 SC were performed to assess their toxicity on aquatic invertebrates (i.e., *Daphnia magna*, *Mysidopsis bahia*, *Crassostrea virginica*). They were already submitted for the first EU evaluation for the Annex I inclusion of the active substance, except two new studies with formulated Dodine as Dodine 400 SC (48-h EC<sub>50</sub> = 28.9 µg a.s./L) and Dodine 544 SC (48-h EC<sub>50</sub> = 25.3 µg a.s./L). The new studies were conducted for bridging purposes.

All of these studies have been evaluated for the current application for the renewal and are considered acceptable by RMS. The relevant information of acute aquatic toxicity to aquatic invertebrates is summarized below (Table 2.9.2.2.2-1).

The new studies not only confirm the similar toxicity of the two formulations to aquatic organisms but also indicate that the toxicity of technical Dodine (48-h EC<sub>50</sub> = 18 µg a.s./L) is not significantly enhanced when formulated to either product. The worst-case EC<sub>50</sub> of 18 µg a.s./L is used for Tier 1 RAC setting while any unresolved acute risk to aquatic invertebrates at Tier 1 level is addressed on the basis of the results of the available mesocosm studies.

**Table 2.9.2.2.2-1. Summary of acute toxicity of dodine to aquatic invertebrates and derivation of RAC for the risk assessment**

| Endpoint                     | Test substance | Toxicity  | Value selected (RAC)            |
|------------------------------|----------------|---|---------------------------------|
| <i>Daphnia magna</i>         | Dodine         | EC <sub>50</sub> = 18 µg a.s./L (mm)                    | EC <sub>50</sub> = 18 µg a.s./L |
| <i>Daphnia magna</i>         | Dodine         | - <sup>a</sup>  |                                 |
| <i>Daphnia magna</i>         | Dodine         | EC <sub>50</sub> = 89 µg a.s./L (mm) <sup>b</sup>       |                                 |
| <i>Mysidopsis bahia</i>      | Dodine         | LC <sub>50</sub> = 390 µg a.s./L (mm)                   |                                 |
| <i>Crassostrea virginica</i> | Dodine         | EC <sub>50</sub> >98 µg a.s./L (mm)                     |                                 |
| <i>Daphnia magna</i>         | Dodine 400 SC  | EC <sub>50</sub> = 123 µg f.p./L = 49 µg a.s./L (mm)    |                                 |
| <i>Daphnia magna</i>         | Dodine 400 SC  | EC <sub>50</sub> = 73.8 µg f.p./L = 28.9 µg a.s./L (mm) |                                 |
| <i>Daphnia magna</i>         | Dodine 544 SC  | EC <sub>50</sub> = 45.8 µg f.p./L = 25.3 µg a.s./L (mm) |                                 |

a new calculations should be submitted by the applicant following the recommendations of OECD 23 (2019)

b In the previous LoEP, the numerical value of the LC<sub>50</sub> endpoint expressed as nominal concentrations is reported although it is stated that it is expressed based on mean measured concentrations. As the measured concentration by end of the study decreased by approx. 60% of the initial concentration, the endpoint should be expressed on the basis of the mean measured concentration, i.e., 89 µg/L.

#### 2.9.2.2.3 Acute (short-term) toxicity to algae or aquatic plants

Studies investigating the toxicity of Dodine (technical and formulated) to green algae (i.e., *Selenastrum capricornutum*) were already submitted for the first EU evaluation for the Annex I inclusion of the active substance. Nevertheless, study re-evaluation indicated that the DAR studies conducted with Dodine technical (██████████ 1993; KCA 8.2.6.1/03) does not meet the validity criteria of the recent OECD testing guideline 201 (2011). In order to address the core data requirement on toxicity to green algae, a new study with *Raphidocelis subcapitata* (*Selenastrum capricornutum*) was conducted with Dodine technical (██████████ 2020; KCA 8.2.6.1/01) generating the critical endpoint for further use in the aquatic risk assessment (i.e., E<sub>r</sub>C<sub>50</sub> = 5.5 µg a.s./L).

Although the DAR study conducted with Dodine formulated as Dodine 400 SC meets the validity criteria of OECD 201 (2011), two new studies investigating the toxicity of Dodine 400 SC (72-h  $E_rC_{50}$  = 12.99  $\mu\text{g a.s./L}$ ) and Dodine 544 SC (72-h  $E_rC_{50}$  = 10.78  $\mu\text{g a.s./L}$ ) to *Desmodesmus subspicatus* have been conducted for bridging purposes. The new studies not only confirm the similar toxicity of the two formulations to aquatic organisms but also indicate that the toxicity of technical Dodine to green algae (72-h  $E_rC_{50}$  = 5.5  $\mu\text{g a.s./L}$ ) is not significantly enhanced when formulated to either product. It is noted that a new statistical analysis of the biological data obtained in the DAR study with Dodine 400 SC was conducted to address the current data requirements according to Commission Regulation (EU) No 283/2013 with respect to  $EC_{10/20}$  endpoints.

As for aquatic invertebrates, any potential Tier 1 risk to algae is addressed at higher-tier level on the basis of the results of the available mesocosm studies.

**Table 2.9.2.2.3-1. Summary of acute toxicity of dodine to algae and derivation of RAC for the risk assessment**

| Endpoint                         | Test substance | Toxicity   | Value selected (RAC)                   |
|----------------------------------|----------------|--|--|
| <i>Selenastrum capricornutum</i> | Dodine         | $E_yC_{50}$ = 1.6 $\mu\text{g a.s./L}$ $E_rC_{50}$ = 5.5 $\mu\text{g a.s./L}$ (mm)   | $E_rC_{50}$ = 5.5 $\mu\text{g a.s./L}$ |
| <i>Selenastrum capricornutum</i> | Dodine 400 SC  | $E_bC_{50}$ = 14.23 $\mu\text{g f.p./L}$ = 5.69 $\mu\text{g a.s./L}$<br>$E_rC_{50}$ = 27.48 $\mu\text{g f.p./L}$ = 10.99 $\mu\text{g a.s./L}$<br>(mm) <sup>a</sup> |  |
| <i>Desmodesmus subspicatus</i>   | Dodine 400 SC  | $E_bC_{50}$ = 4.57 $\mu\text{g f.p./L}$ = 1.79 $\mu\text{g a.s./L}$<br>$E_rC_{50}$ = 33.18 $\mu\text{g f.p./L}$ = 12.99 $\mu\text{g a.s./L}$ (mm)                  |  |
| <i>Desmodesmus subspicatus</i>   | Dodine 544 SC  | $E_bC_{50}$ = 5.70 $\mu\text{g f.p./L}$ = 3.14 $\mu\text{g a.s./L}$<br>$E_rC_{50}$ = 19.56 $\mu\text{g f.p./L}$ = 10.78 $\mu\text{g a.s./L}$ (mm)                  |  |

<sup>a</sup> A statistical re-analysis of study results has been performed to address the Regulations 283/2013 and 284/2013 requirements regarding  $EC_{10}/EC_{20}/EC_{50}$  (together with NOEC) endpoints derivation. The reported endpoints in the table above have been derived from the new statistical analysis.

#### 2.9.2.2.4 Acute (short-term) toxicity to other aquatic organisms

No studies available.

#### 2.9.2.3 Long-term aquatic hazard [equivalent to section 11.6 of the CLH report template]

The relevant information of chronic aquatic toxicity is summarized below (Table 2.9.2.3-1).

**Table 2.9.2.3-1: Summary of relevant information on chronic aquatic toxicity**

| Method  | Species                    | Test material       | Results  | Relevant study                                       | Remarks             | Reference  |

\* Endpoints re-calculated by RMS to fulfil the current recommendations reported in EFSA opinions 2015 and 2019 (EFSA supporting publication 2015:EN-924, 62 pp. and EFSA Supporting publication 2019:EN-1673).

- a In the previous LoEP, a NOEC of 99 µg/L is reported for the long-term toxicity of Dodine to fish. However, effect endpoints from the available study were re-calculated to fulfil the Regulation 283/2013 requirements with regard to EC<sub>10</sub>/EC<sub>20</sub>/EC<sub>50</sub> (together with NOEC) derivation. Regarding fish lengths and weights, the test chamber and not the individual fish, was considered the unit of the new analysis. Further, for these two parameters the results related to the 400 µg a.s./L treatment level were excluded from the new analysis due to the high mortality observed.
- b The EC<sub>10</sub> of 7 µg/L is not reported in the original study report but calculated for the purpose of the renewal of the active substance via statistical re-analysis of the biological data (ToxRat Professional 3.2) to fulfil the Regulation 283/2013 requirements regarding EC<sub>10</sub>/EC<sub>20</sub>/EC<sub>50</sub> endpoints (together with NOEC) derivation.
- c In the previous LoEP, a NOEC of 3200 µg/L based on nominal concentration is reported for *Chironomus riparius* as a result of the long-term water-borne exposure to Dodine. However, in the current evaluation the relevant NOEC has been re-calculated on the basis of the geometric mean measured concentration.
- d The study is considered of providing only supplemental information with regard to the risk assessment

**2.9.2.3.1 Chronic toxicity to fish**

An ELS (Early-Life Stage) study to assess the chronic toxicity of Dodine technical to fish was already submitted for the first EU evaluation for the Annex I inclusion of the active substance (1995; KCA 8.2.2.1/01). Nevertheless, a new statistical analysis of the biological data obtained in the study was conducted to address the current data requirements according to Commission Regulation (EU) No 283/2013 with respect to EC<sub>10/20</sub> endpoints. The new statistical analysis was performed by using the ToxRat Professional 3.2 software and included NOEC, EC<sub>10</sub>, EC<sub>20</sub> and EC<sub>50</sub> estimations. The worst-case NOEC was re-estimated to be 200 µg a.s./L (based on larval survival, length and wet weight) which is higher than the previous EU agreed NOEC of 99 µg a.s./L. The worst-case EC<sub>10</sub>/EC<sub>20</sub> endpoints were estimated to be > 200 µg a.s./L (based on larval survival, length and wet weight), therefore the NOEC of 200 µg a.s./L is further used in the risk assessment. Further details on the model assumptions used in the statistical re-analysis are provided in the study summary.

**2.9.2.3.2 Chronic toxicity to aquatic invertebrates**

A study assessing the chronic toxicity of Dodine technical to *Daphnia magna* was already submitted for the first EU evaluation for the Annex I inclusion of the active substance. Nevertheless, a new statistical analysis of the biological data obtained in the study was conducted to address the current data requirements according to Commission Regulation (EU) No 283/2013 with respect to EC<sub>10/20</sub> endpoints. The new statistical analysis was performed by using the ToxRat Professional 3.2 software and included NOEC, EC<sub>10</sub>, EC<sub>20</sub> and EC<sub>50</sub> estimations. The worst-case NOEC re-estimated is in agreement with the current EU agreed NOEC of 4.4 µg a.s./L (based on the number of offspring produced per survived and introduced parent). The worst-case EC<sub>10</sub> estimated, i.e., 7.0 µg a.s./L (based on the number of offspring produced per introduced parent), is higher than the respective NOEC thus it will not be further considered in the risk assessment.

In addition to the EU peer reviewed study on the chronic toxicity of Dodine to *Daphnia magna*, a new study assessing the chronic toxicity of Dodine technical to *Americamycis bahia* (formerly *Mysidopsis bahia*) under flow-through conditions (i.e., ██████ 2008; KCA 8.2.5.2/01) is available. However, the study does not fulfil the acceptability criteria of the relevant testing guideline [i.e., OPPTS 850.1350 (1996)] and thus it will not be further considered in the effects and risk assessment for aquatic organisms.

As for the acute toxicity, any potential Tier 1 risk of chronic toxicity to aquatic invertebrates is addressed at higher-tier level on the basis of the results of the available mesocosm studies.

A water-sediment study assessing the chronic toxicity of Dodine technical to *Chironomus riparius* was already submitted for the first EU evaluation for the Annex I inclusion of the active substance. Nevertheless, considering the recommendations of EFSA (2019) with regard to the expression of endpoints on the basis of the mass balance calculation, the NOEC for *Chironomus riparius* was re-calculated based on geometric mean concentrations. As no significant effects were determined at either test concentration, EC<sub>10</sub>, EC<sub>20</sub> and EC<sub>50</sub> endpoints are not statistically determined but estimated to be above the highest concentration tested.

#### 2.9.2.3.3 Chronic toxicity to algae or aquatic plants

The DAR study by ██████ (1995; KCA 8.2.6.1/04) included multiple treatments (achieved with partial renewal of test medium at 5-day intervals with maintenance of initial cell density) to simulate the potential build-up of Dodine concentration followed by a 9-day recovery phase (constituted by a 4-day recovery phase in the aged treated medium and a 5-day recovery phase in fresh untreated medium). The validity criterion of mean coefficient of variation for section-by-section growth (OECD 201, 2011) was not met for the exposure period 0-5 d whereas it is not applicable for the exposure periods 5-10 and 10-15 d; however, considering the test design, study findings can still provide valuable information on the toxicity profile of Dodine to green algae.

No study assessing the toxicity of Dodine (technical or formulated) to aquatic macrophytes was submitted for the first EU evaluation for the Annex I inclusion of the active substance. A new study on the effects of Dodine technical to *Lemna gibba* is available resulting in a worst-case E<sub>r</sub>C<sub>50</sub> of 63.2 µg a.s./L based on dry weight for further use in the risk assessment. As for aquatic invertebrates and algae, any potential Tier 1 risk to aquatic macrophytes is addressed at higher-tier level on the basis of the results of the available mesocosm studies.

#### 2.9.2.3.4 Chronic toxicity to other aquatic organisms

Two outdoor mesocosm studies were performed to investigate the effects of multiple applications of Dodine formulated as Dodine 400 SC (██████████ 2007; KCP 10.2.3/04) and Dodine 544 SC (██████████ 2021b; KCP 10.2.3/02), respectively, on freshwater ecosystems (zooplankton, macroinvertebrates, phytoplankton, periphyton and macrophytes excluding vertebrates) as well as to determine the fate of the test substance in the mesocosm systems. The former study by ██████ (2007; KCP 10.2.3/04) was already submitted for the first EU evaluation for the Annex I inclusion of the active substance and considered to be acceptable for use in the higher-tier risk assessment for aquatic organisms. However, considering the recent recommendations of EFSA (2013)<sup>1</sup> and Brock et al. (2015)<sup>7</sup> on the statistical (i.e., MDD) evaluation and effects classification of micro-/mesocosm studies, the study of ██████ (2007; KCP 10.2.3/04) was re-evaluated by ██████ (2021a; KCP 10.2.3/01). The later mesocosm study by ██████ (2021b; KCP 10.2.3/02) has been conducted for the purpose of renewal of the EU approval of Dodine.

Both studies were conducted in Central Europe, i.e., the Netherlands (Wageningen IMARES location Den Helder) and Germany [Fraunhofer Institute for Molecular Biology and Applied Ecology (IME) in cooperation with the test site MESOCOSM GmbH in Homberg-Ohm], respectively. In the former study by ██████ (2007; KCP 10.2.3/04), five levels of the test item, i.e., 3, 6, 16, 41 and 109 µg a.s./L (actual), were tested which were applied

<sup>7</sup> Brock TCM; Hammers-Wirtz M, Hommen U, Preuss TG, Ratte HT, Roessink I, Strauss T, Van den Brink PJ. (2015): The minimum detectable difference (MDD) and the interpretation of treatment-related effects of pesticides in experimental ecosystems. Environ Sci Pollut Res. 22:1160–1174.

twice in a 5-day interval. In the later study by [REDACTED] (2021b; KCP 10.2.3/02), five levels of the test item, i.e., 0.8, 1.6, 3.0, 7.5, 25 µg a.s./L (nominal), were tested which were applied twice in a 7-day interval.

A comparison of the key elements between the two mesocosm studies is provided in Table 2.9.2.3.4-1. Both studies were considered acceptable, however, the endpoints selected by RMS for the risk assessment were only derived from the mesocosms study performed by Homment et al., 2021, due to its higher quality. The following aspects were taken into account for this selection:

- *Differences on establishment phase.* The stabilization phase of [REDACTED] (2007) was considerably smaller respect to that of [REDACTED] (2021b), it could be considered limited (37 days versus >5 years). Therefore, the freshwater community will be significantly more stable in [REDACTED] (2021b). The stress of adaptation of some populations to the mesocosms in [REDACTED] (2007) could camouflage some effect as could see for rotifers (see Vol 3 CP B9.3.3/01 for details). Therefore, sensitivity of [REDACTED] (2007) study could be compromised, the treatment effect camouflaged, leading uncertainties to the results.
- *Better identification of the most sensitive taxa (flagellates) in [REDACTED] (2021b).* In the assessment of [REDACTED] (2007) reported in the Final addendum to the DAR and Additional Report (2010), it was noted that the effect on phytoplankton was not easy to explain, but flagellates were noted to be the most sensitive. The sensitivity of flagellates (and by extension phytoplankton) was confirmed in [REDACTED] (2021b), but with this new study it is possible to evaluate the effect on both phytoplankton and flagellates with much more detail, since the taxonomic identification carried out is better (species level versus flagellate grouping by size)
- *Better representativeness of the most sensitive taxa (flagellates) in [REDACTED] (2021b).* In [REDACTED] (2021b) study, the abundance of sensitive flagellates in phytoplankton is important (good representativeness), being the dominant algae, which makes it possible to identify effects on the structure of the phytoplankton community (for example, diatom growth (indirect effect)).
- *Absence of EPT (Ephemeroptera, Plecoptera and Trichoptera) in [REDACTED] (2007), versus presence of E and T (not P) in [REDACTED] (2021b).* According to the Outcome of the Pesticides Peer Review Meeting on general recurring issues in ecotoxicology (EN-924. 62 pp. and EFSA Supporting publication 2019:EN-1673; EFSA 2019), the representation of EPT is important because they tend to be more sensitive and vulnerable due to their cycles reproductive, although the absence does not invalidate a study, especially if it is shown that they are not the most sensitive groups. [REDACTED] (2021b) mesocosms would show that these taxonomic groups are no more sensitive than plankton (although there are no data for Plecoptera). Nevertheless, it would be an aspect to take into account in terms of the quality of the study.
- *Higher number of replicates in [REDACTED] (2021b) mesocosms.* In [REDACTED] (2007), the number of replicates was the minimum necessary according to the EFSA 2013 guidance.

Therefore, the fully established and more complex community of [REDACTED] (2021b) allowed differentiating toxic effects in more sensitive organisms at lower concentrations and in greater detail than [REDACTED] (2007) study (better representativeness of most sensitive taxa, better taxonomic identification, higher number of experimental replicates, etc.).

Taking into account these differences between both mesocosms studies and concerns, RMS considered that the use in the risk assessment of endpoints obtained from [REDACTED] (2021b) was the most conservative approach. In this sense, an assessment factor of 2 was proposed for ETO-RAC derivation. It is noted that the ETO-RAC of 0.4 µg/L (i.e., Effect class 2 NOEC/2 = 0.8/2 µg/L) it is protective for all model ecosystems tested as it is below the Tier 1 NOEC endpoints (lowest NOEC = 4.4 µg/L for *Daphnia magna*).

The ERO-RAC was based on the effect class 3A concentration at the community-level derived from the mesocosm study of [REDACTED] (2021b) and an assessment factor of 3. It could be considered sufficiently protective taking into account the results obtained in the mesocosm study of [REDACTED] (2007).

Moreover, RMS noted two aspects that could limit the use of ERO-RAC in the risk assessment:

- In the mesocosms study of [REDACTED] (2021b), the formulated product Dodine 544 SC was applied in early summer dates (29/05/2019 and 05/06/2019) and the same occurred for mesocosms study of [REDACTED] (2007). Therefore, **post-harvest applications would not be properly covered by the mesocosms studies.** Considering that the timing of application could influence on recovery of species, **recovery option is considered not acceptable to refine the risk in post-harvest applications.** This aspect would not affect to the use of ETO-RAC, as according EFSA 2019, this endpoint can be considered as independent of the experimental conditions.

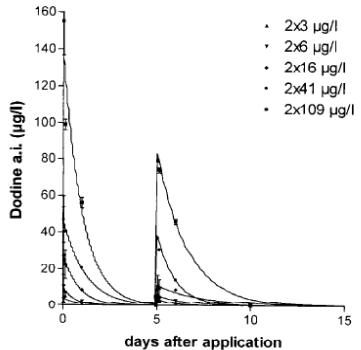

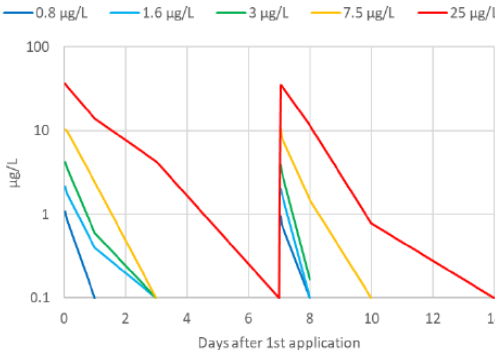

- According to the recommendations of EFSA 2019 (EN-924. 62 pp. and EFSA Supporting publication 2019:EN-1673), when an ERO-RAC is derived, the extrapolation between zones should be considered carefully taking into account the fact that the ability for recovery may vary pending on the agroclimatic conditions. In this case, the mesocosms studies were performed under representative conditions of the Central Zone. Consequently, the suitability of the use of ERO-RAC in the risk assessment or the requirement of a justification for the extrapolation between EU regulatory zones, should be assessed at Member State-level. This aspect would not affect to the use of ETO-RAC, as according EFSA 2019, this endpoint can be considered as independent of the experimental conditions (e.g. the climatic zone).

Table 2.9.2.3.4-1 Comparison between the two mesocosm studies

|                                  | 2007 (KCP 10.2.3/04),<br>2021a (KCP 10.2.3/01)  | 2021b (KCP 10.2.3/02)  | Remarks   |

|--------------------------------|--|---|---|
|                                |  |   | communities to be well-established in the system before the first treatment. If this period is too limited, it can lead to low abundance of some (sensitive or vulnerable) populations which will make any effects more difficult to detect.<br>The stabilization phase of ██████████ (2007) was considerably smaller respect to that of ██████████ (2021b), it could be considered <b>limited</b> (37 days versus >5 years). Therefore, the freshwater community will be significantly more stable in ██████████ (2021b). The stress of adaptation of some populations to the mesocosms in ██████████ (2007) could camouflage some effect as could see for rotifers (see Vol 3 CP B9.3.3/01 for details).  |
| <b>Test units</b>              | Circular glass-fibre tanks with a height of 110 cm and an internal diameter between ca. 200 cm (top) and ca. 190 cm (bottom). The surface area at the sediment-water interface was ca. 3 m <sup>2</sup> . A ca. 10 cm sediment layer was covered by ca. 90 cm deep, water column.  | Stainless-steel enclosures with a diameter of approximately 130 cm (surface approximately 1.3 m <sup>2</sup> ) and a depth of approximately 150 cm. A sediment layer of about 10 cm was covered by a water body of a depth of about 115 cm ± 20 %.  | -   |
| <b>Taxonomic groups tested</b> | Phytoplankton, periphyton, macrophytes, zooplankton, macroinvertebrates. Zooplankton and phytoplankton were introduced into the mesocosms with the natural sediment and water. Macrophytes and macroinvertebrates (gastropods, crustaceans) were introduced.<br><br>Small or medium direct effects could be assessed for 11 plankton taxa, i.e. flagellates (3 – 10 µm), the green algae <i>Scenedesmus</i> sp., unidentified microalgae, and the diatom <i>Stephanodiscus hantzschii</i> in the phytoplankton, <i>Bosmina</i> sp., <i>Ceriodaphnia</i> sp., <i>Daphnia longispina</i> , <i>Simocephalus vetulus</i> , cyclopoid and calanoid copepods, and <i>Filinia longiseta</i> in the zooplankton, as well as for <i>Asellus aquaticus</i> in the macroinvertebrate data set and for cumulative emergence of the chironomid <i>Glyptotendipes pallens</i> and ‘other insects’. Thus, direct small or medium effects could be assessed for 14 taxa. If an assessment of medium to large effects (MDDs < 90 %) is considered acceptable, three additional algae, three rotifer taxa, <i>Gammarus</i> sp. and cumulative emergence of <i>Chaoborus</i> sp., <i>Micropsectra</i> sp. | Phytoplankton, periphyton, macrophytes, zooplankton, macroinvertebrates. All species contained naturally in pond water/sediment.<br><br>Twenty-two diverse taxa showed MDDs < 70 % during or shortly after the applications which is sufficient to detect medium effects according to EFSA (2013): Cryptophyceae (2 species), Chrysophyceae (2 species), Chlorophyceae (in total), Bacillariophyceae (1 diatom species) Cyanophyceae (chlorophyll a), 2 macrophytes, 4 cladocerans, copepods (Cyclopidae), rotifers (2 species), insects (4 species for 3 orders), and snails (2 families). If also the assessment of direct medium to large effects indicated by MDDs < 90 % directly after applications is considered, several other taxa can be included (6 phytoplankton, 2 zooplankton, and 4 macroinvertebrate taxa). | EFSA (2013): The sensitive taxonomic group for fungicides may comprise a wider array of non-vertebrate taxa.<br>Based on the results from Tier 1 laboratory testing algae and aquatic invertebrates are assumed to be the most sensitive taxonomic groups towards Dodine.<br>Both studies provide data for a sufficient number of potentially sensitive populations.<br>Absence of EPT (Ephemeroptera, Plecoptera and Trichoptera) in ██████████ (2007), versus presence of E and T (not P) in ██████████ (2021b). According to the Outcome of the Pesticides Peer Review Meeting on general recurring issues in ecotoxicology (EN-924. 62 pp. and EFSA Supporting publication 2019:EN-1673; EFSA 2019), the representation of EPT is important because they tend to be more sensitive and vulnerable due to their cycles reproductive, although the absence does not invalidate a study, |

|   | 2007 (KCP 10.2.3/04),<br>2021a (KCP 10.2.3/01)  | 2021b (KCP 10.2.3/02)  | Remarks   |
|---|---|--|---|
|   | and <i>Tanytarsus</i> sp. and <i>Glyptotendipes pallens</i> allowed to assess direct effects.   |  | especially if it is shown that they are not the most sensitive groups. (2021b) mesocosms would show that these taxonomic groups are no more sensitive than plankton (although there are no data for Plecoptera). Nevertheless, it would be an aspect to take into account in terms of the quality of the studies. |

### 2.9.2.4 Comparison with the CLP criteria

#### 2.9.2.4.1 Acute aquatic hazard

Table 70: Summary of information on acute aquatic toxicity relevant for classification

| Method  | Species                          | Test material | Results  | Remarks  | Reference  |
|---|----------------------------------|---------------|--|----------|--|
| Acute toxicity to fish<br><br>OECD 203  | <i>Cyprinus carpio</i>           | Dodine        | 96h-LC50 = 0.312 mg a.s./L (mm)                        | Accepted | █ (2006)<br>Please refer to KCA 8.2.1/02   |
| Acute toxicity to aquatic invertebrates<br><br>EPA OPP 72-2 (fulfilled criteria OECD 202) | <i>Daphnia magna</i>             | Dodine        | 48h-EC50 = 0.018 mg a.s./L (mm)                        | Accepted | █ (1992)<br>DAR (2009), EFSA Journal 2010; 8(6):1631<br>Please refer to KCA 8.2.4.1/01 |
| Acute toxicity to algae<br><br>OECD 201   | <i>Selenastrum capricornutum</i> | Dodine        | E <sub>r</sub> C <sub>50</sub> = 0.0055 mg a.s./L (mm) | Accepted | █ (2020)<br>Please refer to KCA 8.2.6.1/01   |

Full acute set was available for odine as there were acute studies on fish, aquatic invertebrates and algae and aquatic plants, covering the three trophic levels (see Table 70). The acute toxicity (LC<sub>50</sub>/ EC<sub>50</sub>) values for all three trophic levels are < 1 mg dodine/L, and algae is the most sensitive trophic level with the 72h-ErC<sub>50</sub> of 0.0055 mg/L.

For classification of a substance in relation to acute aquatic hazard, table 4.1.0 (a) of Annex I of Regulation (EC) No. 1272/2008 should be used. The acute endpoint selected has to be compared with the cut-off value (acute toxicity values ≤ 1 mg/l).

For setting the M factor in relation to aquatic hazard, table 4.1.3 of Annex I of Regulation (EC) No. 1272/2008 should be used. The acute endpoint selected has to be compared with the cut-off values indicated in the mentioned table.

Based on the available data, the lowest acute endpoint is 72h- ErC<sub>50</sub> (*Selenastrum capricornutum*) of **0.0055 mg/L**. This endpoint will establish the M factor needed for the CLP environmental classification.

It is concluded that Dodine does fulfil the criteria for classification and it should be classified according to Regulation (EC) No. 1272/2008 as:

**Aquatic Acute 1** with M factor of 100.

CLP criteria:

- for EC<sub>50</sub> acute toxicity values below or equal to 1 mg/l [E<sub>r</sub>C<sub>50</sub> = 0.0055 mg/L ≤ 1 mg/L] and
- for M factor, acute toxicity value in the range 0.001 < L(E)C<sub>50</sub> ≤ 0.01 mg/L.

#### 2.9.2.4.2 Long-term aquatic hazard (including bioaccumulation potential and degradation)

Table 71: Summary of information on long-term aquatic toxicity relevant for classification

| Method   | Species                          | Test material | Results  | Remarks  | Reference  |
|--|----------------------------------|---------------|--|----------|--|

#### Bioaccumulation

The log Kow values for Dodine are between 1.25 – 1.32 at 20°C, at pH range 4.9 – 9.1, which are less than the CLP log Kow trigger value of > 4 intended to identify substances with a potential to bioaccumulate under CLP criteria. According to CLP guidance, measured estimates should be used in preference when available to conclude on the bioaccumulation potential of a substance (BCF ≥ 500 indicates bioaccumulation potential). Since, no studies are available to establish measured BCF estimates, log Kow data have been used to conclude on the potential for bioaccumulation of Dodine. log Kow estimates is lower than the CLP trigger value of 4, Dodine is considered to have low potential to bioaccumulate.

#### Degradation

A ready biodegradability test (OECD test guideline 301B) shows Dodine being not readily biodegradable for purposes of classification as the pass level criteria of ready biodegradation test (70% of DOC removal or 60% of theoretical oxygen demand) within 28 days was not reached.

Dodine is hydrolytically stable at pH values of 4, 7 and 9 at 50°C in the dark over a period of 5 days, with half live 1 year at 25°C.

Regarding photodegradation, degradation of Dodine was slowly (82.1% of AR after 30 days), whereas in irradiated natural water Dodine degraded down to 56.9% of AR after 28 days. Dodine was stable in the dark controls of both water types. The half-live values in natural summer sunlight days at 40°N for Dodine was found to be 27 and 104 days for DT<sub>50</sub> and DT<sub>90</sub> respectively for natural water.

In an aerobic mineralization study Dodine degraded rapidly and ultimately mineralized to CO<sub>2</sub>, with DT<sub>50</sub> values of 2.3 days. In the water-sediment study, the whole system half live in a natural water/sediment study is 0.36 days of Dodine and mineralisation to CO<sub>2</sub> is the major degradation process. Dodine can be considered as rapidly degradable in the aquatic environment from the aerobic mineralization and water/sediment system studies carried out.

Overall, degradation information does provide data to show that Dodine is ultimately degraded to > 70% within 28 days (equivalent to a half-life of less than 16 days) or being transformed to non-classifiable products. Therefore, Dodine is considered to be **Rapidly degradable** according to the CLP criteria.

### Toxicity

Long-term aquatic toxicity data regarding technical Dodine are available for fish, aquatic invertebrates including sediment dwelling organisms, algae and other aquatic plants (i.e., there is appropriate data for all three trophic levels that need to be assessed for CLP classification).

For classification of a substance in relation to chronic aquatic hazard, table 4.1.0 (b) of Annex I of Regulation (EC) No. 1272/2008 should be used. The acute endpoint selected has to be compared with the cut-off value setting in the mentioned table above.

For setting the M factor in relation to aquatic hazard, table 4.1.3 of Annex I of Regulation (EC) No. 1272/2008 should be used. The chronic endpoint selected has to be compared with the cut-off values indicated in the mentioned table, taking into account the degradability of the substance.

The lowest ErC<sub>10</sub> value is the measured **72h-ErC<sub>10</sub> of 0.0019 mg a.s./L** for algae (*Selenastrum capricornutum*). This is > 0.001 mg/L but ≤ 0.01 mg/L, and since Dodine is considered to be ‘rapidly degradable’ as well as not potentially bioaccumulative, it should be classified according to Regulation (EC) No. 1272/2008 as:

**Aquatic Chronic 1** with a chronic M-factor of 1.

CLP criteria:

- for EC<sub>50</sub> chronic toxicity values below or equal to 0.1 mg/l [ErC<sub>10</sub>(72h) = 0.0019 mg/L ≤ 0.1 mg/L] and
- for M factor, Dodine is considered rapidly degradable substance and the chronic toxicity value is in the range 0.001 < L(E)C<sub>10</sub> ≤ 0.01 mg/L [ErC<sub>10</sub> (72h) = 0.0019 mg a.s./L].

### **2.9.2.5 Conclusion on classification and labelling for environmental hazards**

Taking into account all the information and the assessment summarized in the previous sections 2.9.2.4.1 and 2.9.2.4.2, the following classification class and category can be concluded for this active substance dodine, in accordance with Regulation (EC) 1272/2008:

| CLP Annex ref | Hazard class                         | Proposed classification                              | Proposed SCLs and/or M-factors     | Current classification <sup>1</sup>  | Reason for no classification <sup>2</sup>             |
|---------------|--------------------------------------|--|------------------------------------|--------------------------------------|---|
| 4.1           | Hazardous to the aquatic environment | Aquatic Acute 1<br>H400<br>Aquatic Chronic 1<br>H410 | M-factor = 100<br><br>M-factor = 1 | Aquatic Acute 1<br>Aquatic Chronic 1 | -   |
| 5.1           | Hazardous to the ozone layer         | -  | -                                  | -                                    | Data conclusive but not sufficient for classification |

<sup>1</sup>) Including specific concentration limits (SCLs) and M-factors

<sup>2</sup>) Data lacking, inconclusive, or conclusive but not sufficient for classification

**Labelling:**      Signal word: Warning

Hazard statements: Very toxic to aquatic life with long lasting effects (H410)

Precautionary statements:

P273: Avoid release to the environment  
 P391: Collect spillage  
 P501: Dispose of contents/container in accordance with national hazardous waste regulations

Pictogram: GSH09

The following additional statements are recommended.

- EUH401: To avoid risks to human health and the environment, comply with the instructions for use.

### 2.9.3 Summary of effects on arthropods

#### 2.9.3.1 Effects on bees

Studies investigating the acute oral and contact toxicity of Dodine (technical and formulated as Dodine 400 SC) to bees were already submitted for the first EU evaluation for the Annex I inclusion of the active substance. Nevertheless, new studies to address the acute toxicity of the current representative formulation, i.e., Dodine 544 SC, to bees as well as the requirements of Regulations (EU) No 283/2013 and 284/2013 regarding data on the chronic oral toxicity to adult honeybees and honeybee larvae have been conducted and submitted for the purpose of the renewal of the approval of the active substance. In addition to the new Tier 1 studies, two higher-tier effect studies (i.e., semi-field tunnel tests) conducted with the formulation Dodine 544 SC were also submitted. Considering the available, complete data set, the acute oral LD<sub>50</sub> > 55.7 µg a.s./bee, the contact LD<sub>50</sub> > 100 µg a.s./bee, the LDD<sub>50</sub> of 1.86 µg a.s./bee/d (relevant for the chronic toxicity to adult bees) and the ED<sub>10</sub> of 5.7 µg a.s./larva (relevant for the chronic toxicity to honeybee larva) were used in the Tier 1 bee risk assessment.

**Table 2.9.3.1-1: Effects of Dodine and the representative formulations on honeybees.**

| Test substance                | Test species          | Exposure system                           | Endpoint  | Reference   | Endpoint used in the risk assessment                        |

| Dodine 544 SC   | Semi-field (tunnel) test in Southern Europe (Spain), assessment of effects on honeybee <i>Apis mellifera</i> after two foliar applications of Dodine 544 SC with each at 900 g a.s./ha in a 7-day interval (±1 day) on flowering Phacelia ( <i>Phacelia tanacetifolia</i> ) under semi-field conditions; No adverse effects were assessed on honeybees including their brood nor the survival of the honeybee colony.   |                 |  | █ (2020)<br>Please refer to KCP 10.3.1.5/01                   | No adverse effects at 2 × 0.9 g a.s./ha, 7-day interval (±1 day)  |
| Dodine 544 SC   | Semi-field (tunnel) test in Central Europe (Germany), assessment of effects on honeybee <i>Apis mellifera</i> after two foliar applications of Dodine 544 SC with each at 900 g a.s./ha in a 7-day interval (±1 day) on flowering Phacelia ( <i>Phacelia tanacetifolia</i> ) under semi-field conditions; Effects on mortality were observed in the Germany trial for the exposure period when the application was done during the bee flight, however for the overall exposure there were not any significant effect between test items I, II and control. Mitigation measures could be proposed to avoid the effects on mortality observed during the exposure period. i.e. <i>to protect bees and other pollinating insects do not use where bees are actively foraging</i> . Overall, no adverse effects on honeybee brood or honeybee colony survival were observed. |                 |  | █ (2021)<br>Please refer to KCP 10.3.1.5/02                   | Effects on mortality were observed in one trial for the exposure period when the application was done during the bee flight, however for the overall exposure there were not any significant effect between test items I, II and control. at 2 × 0.9 g a.s./ha, 7-day interval (±1 day) |

### 2.9.3.2 Effects on non-target arthropods other than bees

Studies assessing the effects to non-target arthropods other than bees were available with Dodine formulated as Dodine 400 SC and Dodine 544 SC. All studies, standard and extended laboratory tests, conducted with the formulation Dodine 400 SC were already submitted for the first EU evaluation for the Annex I inclusion of the active substance. In addition to the already EU peer reviewed studies, two new laboratory tests with the standard species *Aphidius rhopalosiphi* and *Typhlodromus pyri* have been conducted with the current representative formulation, i.e., Dodine 544 SC. The endpoints derived from the later studies, i.e., LR<sub>50</sub>/ER<sub>50</sub> > 1530 g a.s./ha for

*Aphidius rhopalosiphi* and the endpoint derived for the previous study  $LR_{50} > 900$  g a.s./ha for *Typhlodromus pyri*, were retained in the risk assessment for non-target arthropods.

**Table 2.9.3.2-1: Effects of Dodine and the representative formulations on non-target arthropods**

| Test substance                              | Test species                     | Exposure system      | Endpoint   | Reference   | Endpoint used in the risk assessment  |

## 2.9.4 Summary of effects on non-target soil meso- and macrofauna

### 2.9.4.1 Effects on earthworms

Studies on the acute toxicity of Dodine technical and the chronic toxicity of Dodine formulated as 400 g/L SC to earthworms (*Eisenia fetida*) were already submitted for the first EU evaluation for the Annex I inclusion of Dodine. No new studies on earthworms have been conducted for the purpose of renewal of the approval of the active substance.

A new statistical analysis of the biological data obtained in the available chronic toxicity study was conducted to address the current data requirements according to Commission Regulations (EU) No 283/2013 and 284/2013 with respect to EC<sub>10/20</sub> endpoints. The new statistical analysis was performed by using the ToxRat Professional 3.2 software and included NOEC, EC<sub>10</sub>, EC<sub>20</sub> and EC<sub>50</sub> estimations. The worst-case NOEC was re-estimated to be 66.1 mg a.s./kg dw (based on reproductive performance) while the worst-case EC<sub>10</sub> endpoint was calculated to be 62.4 mg a.s./kg dw (based on reproductive performance). Thus, the latter endpoint was selected to be used in the risk assessment. However, **details of statistical re-evaluation was not submitted to RMS, therefore, a data gap is set. The EC<sub>10</sub> = 62.4 mg a.s./kg dw is considered provisional pending on the submission of the statistical re-evaluation of ██████████ 2007 (KCP 10.4.1.1/01).**

A summary of the available studies is presented in Table 2.9.4.1-1.

**Table 2.9.4.1-1 Effects of the representative formulation on earthworms**

| Test substance                        | Test species          | Exposure system  | Endpoint  | Reference                            | Endpoint used in the risk assessment   |

| Dodine technical                      | <i>Eisenia fetida</i> | Mixed into substrate 14 d, acute 10.1% w/w sphagnum moss content | LC <sub>50</sub> = 547 mg a.s./kg dw  | ██████████ (1995)<br>KCA 8.4.1/01    | -                                      |
| <b>Chronic toxicity to earthworms</b> |                       |  |   |                                      |  |
| Dodine 400 SC                         | <i>Eisenia fetida</i> | Mixed into substrate 56 d, chronic 10% w/w sphagnum peat content | NOEC = 172 mg f.p./kg dw corresponding to 66.1 mg a.s./kg dw<br>EC <sub>10</sub> = 62.4 mg a.s./kg dw | ██████████ (2007)<br>KCP 10.4.1.1/01 | EC <sub>10</sub> = 62.4 mg a.s./kg dw* |

a.s. active substance  
f.p. formulated product

\* The EC<sub>10</sub> = 62.4 mg a.s./kg dw is considered provisional pending on the submission of the statistical re-evaluation of [REDACTED] 2007 (KCP 10.4.1.1/01).

Although no specific toxicity data on the current representative formulation, i.e., Dodine 544 SC, have been generated, further toxicity testing with earthworms is not required as it is possible to extrapolate from the available study with the formulation Dodine 400 SC provided that the respective endpoint is expressed as active substance equivalents. Please refer to Volume 4 “Confidential Information” for further details. Moreover, the ecotoxicological equivalence between the two formulations is confirmed based on the results of bridging studies conducted with aquatic non-vertebrate species (i.e., *Daphnia magna* and *Desmodesmus subspicatus*). Considering all available information, RMS agrees that the formulation Dodine 400 SC could be considered as a surrogate for assessing the toxicity of Dodine 544 SC.

#### 2.9.4.2 Effects on non-target soil meso- and macrofauna (other than earthworms)

No studies on the effects of Dodine (technical or formulated) on non-target soil meso- and macrofauna other than earthworms were conducted for the first EU evaluation for the Annex I inclusion of Dodine. According to Commission Regulation (EU) No 284/2013, testing shall be carried out on both *Folsomia candida* and *Hypoaspis aculeifer* if either of the following conditions are met: (i) the plant protection product under concern is applied directly to soil as soil treatment either as a spray or as a solid formulation, (ii) concern is raised regarding potential unacceptable effects to the standard non-target arthropod species *Aphidius rhopalosiphi* and *Typhlodromus pyri*. Given that Dodine 544 SC is intended to be applied as a foliar spray and no unacceptable risk to non-target arthropods is concluded on the basis of the Tier 1 risk assessment conducted, typically, no further testing with either *Folsomia candida* or *Hypoaspis aculeifer* is required. Nevertheless, testing of Dodine 544 SC on both species has been conducted under standard (i.e., *Folsomia candida*, *Hypoaspis aculeifer*) and refined (i.e., *Folsomia candida*) exposure conditions. A summary is provided in the following table :

**Table 2.9.4.2-1 Effects of Dodine and the representative formulation on non-target soil meso- and macrofauna (other than earthworms)**

| Test substance | Test species               | Exposure system  | Endpoint   | Reference                             | Endpoint used in the risk assessment                           |

#### 2.9.5 Summary of effects on soil nitrogen transformation

The effects of Dodine formulated as Dodine 400 SC on soil microbial activity (nitrogen turnover and short-time respiration) are adequately presented and discussed in Volume 3 CP Point B.9.9.

A study on the effects of Dodine formulated as 400 g/L SC on soil microbial activity (nitrogen turnover and short-time respiration) was already submitted for the first EU evaluation for the Annex I inclusion of Dodine (2002 ; KCP 10.5/01). No new studies have been conducted for the purpose of renewal of the approval of Dodine.

Based on the results of (2002, KCP 10.5/01), Dodine 400 SC has non unacceptable long-term effects (no effects  $\geq 25\%$ ) on soil nitrate content and soil nitrate formation rate of soil microflora at the test concentration of 12 mg a.s./kg dry soil. The results of the study are considered supportive only. A data gap has been set to the applicant to submit the soil nitrogen transformation rate expressed in mg nitrate/kg dry weight soil/day between each measurement day for control and all tested concentrations in order to determine the difference in transformation rates as recommended by the OECD 216.

**Table 2.9.5-1 Effects of Dodine and the representative formulations on soil microorganisms**

| Test substance | Endpoint         | Exposure system               | Results  | Reference          | Endpoint used in the risk assessment |
|----------------|------------------|-------------------------------|--|--------------------|--------------------------------------|
| Dodine 400 SC  | N-transformation | 28 d, aerobic loamy sand soil | No effects $\geq 25\%$ at 9000 g a.s./ha (corresponding to 12 mg a.s./kg dw) after 28 days | (2002) KCP 10.5/01 | 12 mg a.s./kg dw                     |

## 2.9.6 Summary of effects on terrestrial non-target higher plants

Studies on the effects of Dodine technical and formulated as 400 g/L SC on the vegetative vigour and seedling emergence of non-target terrestrial plants were already submitted for the first EU evaluation for the Annex I inclusion of Dodine. In addition to the already EU peer reviewed studies, two new studies assessing the effects of the current representative formulation, i.e., Dodine 544 SC, on the vegetative vigour and the seedling emergence of non-target higher plants have been conducted.

The effects of Dodine (technical and formulated) to terrestrial non-target higher plants are adequately presented and discussed in Volume 3 CA B9 Point 9.6 and Volume 3 CP B9 Point B.9.11.

(2011b) determined the induced effect of a single application of Dodine 544 SC with respect to the seedling emergence and the seedling growth in a variety of terrestrial plants. The study was performed as a limit test at 0 and 15 kg a.i./ha for six plant species. The most sensitive parameter and plant species was wet weight for ray-grass, lettuce and cabbage: mean weight was reduced by more than 30% as compared to the controls. Significant effects have been observed at the limit concentration, therefore, no endpoint could be derived from the test. Moreover, several deviations from OECD 208 have been noted and the study has not been conducted under GLP. All in all, RMS considers that the study is not valid for risk assessment purposes.

(2011a) determined the induced effects of Dodine 544 SC on terrestrial plant growth. The study was performed as a limit test at 0 and 15 kg a.i./ha for nine plant species. The plants were grown from seeds on a natural sandy loam soil to the 2- to 4-true leaf stage. The test item and control treatments were then sprayed on the plant and leaf surfaces at appropriate rates. After the application, the plants were evaluated against water control plants for effects on vigour and growth at various time intervals until 21-28 days after treatment. The plants died within few days for onion, lettuce, radish, tomato, cucumber and cabbage. Ray-grass, oat and soybean survived until the end of the test, but both plant height and plant weight were significantly reduced as compared to the controls. The phytotoxicity consisted of dwarfism and necrosis. Since significant effects above 50% has been observed at the limit concentration, no endpoint could be derived from the test. Moreover, several deviations from OECD 227 has been noted and no GLP statement was provided. All in all, RMS considers that the study is not valid for risk assessment purposes.

(2007) determined the effects of Dodine 400 SC on the vegetative vigour, growth and health of three non-target plant species: cabbage (*Brassica oleracea*), cucumber (*Cucumis sativus*) and radish (*Raphanus sativus*)

following one leaf application in comparison to a blank control (deionised water). The experimental design consisted of seven treated groups each one representing a different dodine applied rate at growth stage BBCH 12-14. Based on the results obtained under worst case greenhouse conditions, the ER<sub>50</sub> was > 4.5 kg a.s./ha for all species tested. However, seedling emergence data were not included in the report, therefore, RMS could not check all validity criteria.

█ (1993a) evaluated the effects of Dodine at its maximum label rate of 2.9 kg a.s./ha on vegetative vigour on ten non-target plant species during critical stages in their development. The validity criteria according to the OECD 227 (the seedling emergence is at least 70 %) cannot be validated, as no data on seedling emergence were reported. However, a parallel study on seedling emergence (█ 1993b) was performed under the same conditions (same study location, test facility, plant species, soil, planting pattern, number of seed per pot and replicates, similar dates and environmental conditions of greenhouse). The lot number of the tested seeds were the same with two exceptions, cucumber and lettuce. Moreover, in █ (1993b), seedling emergence for tomato and lettuce failed in the original study, and it as repeated for this species at a different planting depth. Therefore, taking into account the results on seedling emergence of █ (1993b), RMS is of the opinion that this validity criteria could be considered as met for all expecies excetp to lettuce, tomato and cucumber.

█ (1993b) evaluated the effects of Dodine at its maximum label rate of 2.9 kg as/ha on seedling emergence and other growth characteristics on ten non-target plant species during critical stages in their development. No noticeable phytotoxicity was noted on any day of evaluation. No effects > 25% on phytotoxicity, plant height and dry plant weight were reported. Therefore, it is concluded that the ER<sub>50</sub> was > 2.9 kg a.s./ha for all species tested except to lettuce, tomato and cucumber.

█ (1993c) studied whether detrimental effects of 25% or greater occurred on one or more plant species after application of dodine technical at the maximum rate of 2.9 kg as/ha. The study was performed in compliance with GLP and following EPA OPP 122-1 guideline (Terrestrial Plant Toxicity Tier I (seedling emergence)). This protocol differs substantially from OECD 208, therefore, the study is considered as supplementary information only.

### 2.9.7 Summary of effects on other terrestrial organisms (flora and fauna)

No data available.

### 2.9.8 Summary of effects on biological methods for sewage treatment

Two studies assessing the effects of Dodine technical to biological methods for sewage treatment by measuring the activated sludge respiration inhibition are available. One study was already submitted for the first EU evaluation for the Annex I inclusion of Dodine while the other study was conducted for the purpose of the renewal of the approval of the active substance. Both studies were conducted according to OECD testing guideline 209 and meet the respective validity criteria. The lowest EC<sub>50</sub> and EC<sub>10</sub> endpoints of 22.4 and 3 mg a.s./L for activated sludge respiration inhibition are derived from the newly submitted study.

Table 2.9.8-1 Effects on biological methods for sewage treatment

| Test substance | Endpoint                                | Exposure system  | Results  | Reference                       |
|----------------|---|--|--|---------------------------------|
| Dodine         | Activated sludge respiration inhibition | 30 min, activated sludge from municipal sewage plant     | EC <sub>50</sub> = 52 mg as/L<br>EC <sub>10</sub> = 9 mg/L | ██████████ (2001)<br>KCP 8.8/02 |
| Dodine         | Activated sludge respiration inhibition | 3 h, activated sludge of a predominantly domestic sewage | EC <sub>50</sub> = 22.4 mg/L<br>EC <sub>10</sub> = 3 mg/L  | ██████████ (2020)<br>KCP 8.8/01 |

## 2.9.9 Summary of product exposure and risk assessment

### 2.9.9.1 Summary of risk assessment for bird and other terrestrial vertebrates

#### Birds

The risk assessment for effects on birds is carried out according to the Guidance Document on Risk Assessment for Birds and Mammals on request from EFSA (EFSA Journal 2009; 7(12): 1438). The acute and long-term risks of Dodine formulated as Dodine 544 SC to birds were assessed from toxicity exposure ratios between toxicity endpoints, derived from studies with Dodine technical and estimated exposure based on the maximum residues occurring on food items following applications according to the proposed use pattern.

#### Acute dietary risk assessment

The geometric mean of the LD<sub>50</sub> on mallard duck and the LD<sub>50</sub> on bobwhite quail as derived from the available short-term dietary studies, i.e., 522.8 mg a.s./kg bw, is used in the regulatory acute risk assessment for birds. All TER<sub>A</sub> values for Dodine calculated for the relevant exposure scenarios exceed the trigger of 10 at screening step, indicating no potential acute risk for birds following the representative uses of Dodine 544 SC in apples/pear, cherry and peach (Tables 2.9.9.1-1 and 2.9.9.1-2).

**Table 2.9.9.1-1 Screening assessment of the acute risk for birds after the use of Dodine 544 SC in apples/pear and cherry (2 × 0.68 kg a.s./ha, 21-day interval)**

| Intended use                     |                          | Apples/pear, cherry |                   |      |                              |                  |

MAF: multiple application factor calculated in line with Appendix H EFSA/2009/1438 for 2 applications with a 21-day interval and assuming a default foliar DT<sub>50</sub> value of 10 days; TWA: time weighted factor (default); DDD: daily dietary dose. TER values shown in **bold** fall below the relevant trigger.

For these two types of diet guild (granivorous and small insectivorous birds), a higher tier risk assessment is performed by considering focal species, i.e., a real species that actually occur in the crop when the pesticide is being used, and their ecological properties (PT: Proportion of diet obtained in the treated area), by refining the residue decline (DT<sub>50</sub>) in potential food items of the identified focal species and last by incorporating in the exposure estimation the interception by the crop. However, the refinement for the small insectivorous birds of focal species, PT and DT<sub>50</sub> are only reliable in the Central Zone. The calculated higher tier TER<sub>LT</sub> values exceed the trigger of 5 for small insectivorous birds for the intended uses on apple/pear and cherry in the Central Zone and granivorous birds for all the intended uses (Tables 2.9.9.1-8 and 2.9.9.1-9).

**Table Table 2.9.9.1-8 Refined long-term TER calculations for small insectivorous birds after the use of Dodine 544 SC in apples/pear, cherry and peach (application on spring-summer) in Central Zone**

| TER                              | 7.8   |  | 5.9  | 5.9                                  |

Therefore, **no unacceptable long-term risk to birds** following the representative uses of Dodine 544 SC in **apples/pear and cherry in the Central Zone** based on the outcome of the higher tier risk assessment.

However, the following should be considered : all refinements (except interception value) were representative for the Central Zone, their extrapolation to other regulatory zones needs further justification/applicability may need further consideration at Member State level.

#### *Drinking water risk assessment*

Based on the ratios of the effective application rate to the relevant toxicity endpoints, an acceptable risk is demonstrated for birds due to exposure to Dodine via contaminated drinking water in puddles (puddle scenario). Further, considering the representative uses of Dodine 544 SC in orchards, no risk to birds is expected via exposure to contaminated drinking water in leaf whorls (leaf scenario).

#### *Secondary poisoning*

The log P<sub>ow</sub> of Dodine does not exceed the trigger value of 3; thus, a risk assessment of secondary poisoning for earthworm- and fish-eating birds is not required.

#### **Mammals**

Studies on the acute oral and reproductive/long-term toxicity of Dodine technical to mammals as well as a study investigating the long-term effects of Dodine 400 SC on common voles under field conditions were already submitted for the first EU evaluation for the Annex I inclusion of the active substance. For the renewal of the approval of the active substance a study assessing the acute oral toxicity of the representative product Dodine 544

SC to mammals (i.e., rats) and a semi-field study investigating the long-term effects on common voles in treatment enclosures following Dodine 544 SC applications are newly submitted.

The risk assessment for effects on mammals is carried out according to the Guidance Document on Risk Assessment for Birds and Mammals on request from EFSA (EFSA Journal 2009; 7(12): 1438). The acute and long-term risks of Dodine formulated as Dodine 544 SC to mammals were assessed from toxicity exposure ratios between toxicity endpoints, derived from studies with Dodine technical and estimated exposure based on the maximum residues occurring on food items following applications according to the proposed use pattern.

#### *Acute dietary risk assessment*

The geometric mean of the two LD<sub>50</sub> endpoints on the acute oral toxicity of Dodine technical to rats and, i.e., 1073 mg a.s./kg bw, is used in the regulatory acute risk assessment for wild mammals.

At screening step, acute TERs for mammals were below the trigger values for the representative uses in apples/pear and cherry ( $2 \times 0.68$  kg a.s./ha, 21-day interval). Acute TERs for mammals exceeded the relevant trigger of 10 for the intended uses in peach ( $2 \times 0.9$  kg a.s./ha, 21-day interval). At Tier 1, a high risk is still identified for Small herbivorous mammal “vole” at BBCH < 10 (application crop directed or not crop directed) and BBCH 10-19. Therefore, further refinements are required for the intended use on peach.

#### *Long-term dietary risk assessment*

The lowest NOAEL of 26 mg a.s./kg bw/d as derived from the two-generation study in rats is used in the regulatory long-term/reproductive risk assessment for mammals.

At screening step, the long-term TER values for Dodine were below the trigger value of 5 for all the intended uses. At Tier 1, a high risk is still identified for the following scenarios :

#### **Applications on apples/pear ( $2 \times 0.68$ kg a.s./ha, 21-day interval) :**

- Large herbivorous mammal “lagomorph » at BBCH < 10 (application crop directed or not crop directed)
- Small herbivorous mammal “vole” from BBCH < 10 to  $\geq 40$
- Frugivorous mammal “dormouse” at BBCH 71-79

#### **Applications on cherry ( $2 \times 0.68$ kg a.s./ha, 21-day interval):**

- Small herbivorous mammal “vole” at BBCH  $\geq 40$
- Frugivorous mammal “dormouse” at BBCH 71-79

#### **Applications on peach ( $2 \times 0.9$ kg a.s./ha, 21-day interval):**

- Large herbivorous mammal “lagomorph » at BBCH < 10 (application crop directed or not crop directed) and BBCH 10 - 19
- Small herbivorous mammal “vole” from BBCH < 10 to  $\geq 40$

For the above-mentioned exposure scenarios, a higher tier risk assessment was performed by refining the information on their diet composition (PD) and the residue decline (DT<sub>50</sub>) or the magnitude of residues (i.e., RUD) in potential food items, by incorporating in the exposure estimation the interception by the crop. The results of the available field effect studies could not be considered in the risk assessment as their statistical power were missing. Based on the higher tier information available, no unacceptable long-term risk to mammals is expected following the representative uses of Dodine 544 SC in orchards in Central Zone, except for :

- apple/pear at BBCH<10 (unacceptable for vole identified)
- cherry at postharvest (unacceptable for vole and dormouse identified)
- peach (unacceptable for vole identified).

Refinements were representative for the Central Zone, their extrapolation to other regulatory zones requires further justification and their applicability may need further consideration at Member State level.

#### *Drinking water risk assessment*

Based on the ratio of the effective application rate to the relevant toxicity endpoints, an acceptable risk is demonstrated for mammals due to exposure to Dodine via contaminated drinking water in puddles (puddle scenario). Further, considering the representative uses of Dodine 544 SC in orchards, no risk to mammals is expected via exposure to contaminated drinking water in leaf whorls (leaf scenario).

#### *Secondary poisoning*

The log  $P_{ow}$  of Dodine does not exceed the trigger value of 3; thus, a risk assessment of secondary poisoning for earthworm- and fish-eating mammals is not required

### 2.9.9.2 Summary of risk assessment for aquatic organisms

The risk assessment were performed following the current EFSA guidance on aquatic organisms (2013). PECsw/sed calculations provided by the applicant were performed for two applications of the representative formulation Dodine 544 SC in orchards at 0.68 and 0.9 kg a.s./ha, in a 21-day interval.

New PECsw/sed calculations of dodine were developed by RMS (see Vol 3CP 8.5). Based on those new PECsw/sed and the adequate endpoints (summarized below), PEC/RAC ratios for dodine have been re-calculated by RMS. For these calculations, only the relevant global maximum FOCUS Steps 3 and 4 PECsw have been considered.

**Table 2.9.9.2-1: Endpoints used in the risk assessment for aquatic organisms.**

| Taxonomic group/exposure regime | Tier I RAC [ $\mu\text{g a.s./L}$ ] | Higher-tier RAC [ $\mu\text{g a.s./L}$ ]    |
|---------------------------------|-------------------------------------|---|
| Fish/acute                      | 3.12                                | 12.55 <sup>a</sup>                          |
| Fish/long-term                  | 17                                  | -   |
| Aquatic invertebrates/acute     | 0.18                                | ETO-RAC = 0.4<br>ERO-RAC <sup>b</sup> = 2.5 |
| Aquatic invertebrates/long-term | 0.44                                |   |
| Algae                           | 0.55                                |   |
| Aquatic invertebrates           | 8.4                                 |   |
| Sediment dwellers/long-term     | 88.3                                | -   |

<sup>a</sup> Preliminary endpoint, pending on the submission of the statistical robustness of some LC50 by the applicant.

<sup>b</sup> derived from the mesocosm study of ██████████ (2021b) by applying an assessment factor of 3 to the Effect class 3A NOEAEC = 7.5  $\mu\text{g a.s./L}$

#### STEP 3

For the intended use of Dodine 544 SC in **apples/pear** (2 x 0.68 kg a.s./ha), both early and late applications, a potential risk for acute and prolonged exposure of aquatic organisms was found, independently if multiple or single applications are considered (PEC/RAC ratios based on both Tier 1 and Higher Tier endpoints were above the relevant trigger value of 1). When mesocosm ERO-RAC is considered, no unacceptable risk for aquatic organisms can be concluded for scenarios D4 pond, D5 pond and R1 pond for late applications. However, further refinement for all scenarios was required.

For **cherry** (2 x 0.68 kg a.s./ha), a potential risk for acute and prolonged exposure of aquatic organisms was found for summer, late and post-harvest applications, independently if multiple or single applications are considered (PEC/RAC ratios based on both Tier 1 and Higher Tier endpoints were above the relevant trigger value of 1). When mesocosm ERO-RAC of 2.5  $\mu\text{g/L}$  is considered, no unacceptable risk for aquatic organisms can be concluded for scenarios D4 pond, D5 pond and R1 pond for summer and late applications. However, further refinement for all scenarios was required.

For **peach** (2 x 0.9 kg a.s./ha), a potential risk for acute and prolonged exposure of aquatic organisms was found for summer, late and post-harvest applications. As occurred for the other uses, when mesocosm ERO-RAC of 2.5  $\mu\text{g/L}$  is considered, no unacceptable risk for aquatic organisms can be concluded for scenarios D4 pond, D5 pond and R1 pond for late applications. However, further refinement for all scenarios was required.

Single applications led the worst-case PECsw values respect to multiple applications, therefore, only PEC/RAC results at FOCUS STEP 3 were presented below (for details of multiple applications, see Vol 3CP 9.4).

**Table 2.9.9.2-2: Aquatic organisms: acceptability of risk (PEC/RAC < 1) for the active substance Dodine for each organism group based on FOCUS Steps 3 calculations for the use of Dodine 544 SC in apples/pear (2 x 0.68 kg a.s./ha, Pome/stone fruit, early application)**

AF: Assessment factor; PEC: Predicted environmental concentration; RAC: Regulatory acceptable concentration

PEC/RAC ratios above the relevant trigger of 1 are shown in bold

\* In SWASH the user needs to select the crop on which the compound is intended to be used. As spray drift deposition varies considerably for fruit trees and vines, a distinction has been made between their early and late crop growth stage, representing respectively a growth stage with no or few leaves and a growth stage in which the leaves are well developed. The distinction between early and late references is made to the BBCH-codes as mentioned in Table 2.4.2-1 of SW GD. Late applications are only defined up to BBCH 89. However, post-harvest application are made between BBCH 90 and 99, from 50% leaf falling till after leaf falling (autumn). Therefore, in line with groundwater risk assessment, the same drift as an early application should be applied. Consequently, RMS considers that pome/stone fruit early applications FOCUS SW crop should be selected for modelling post-harvest uses.

**Table 2.9.9.2-7: Aquatic organisms: acceptability of risk (PEC/RAC < 1) for the active substance Dodine for each organism group based on FOCUS Steps 3 calculations for the use of Dodine 544 SC in peach (2 × 0.9 kg a.s./ha, Pome/stone fruit, early application)**

AF: Assessment factor; PEC: Predicted environmental concentration; RAC: Regulatory acceptable concentration  
 PEC/RAC ratios above the relevant trigger of 1 are shown in bold

\* In SWASH the user needs to select the crop on which the compound is intended to be used. As spray drift deposition varies considerably for fruit trees and vines, a distinction has been made between their early and late crop growth stage, representing respectively a growth stage with no or few leaves and a growth stage in which the leaves are well developed. The distinction between early and late references is made to the BBCH-codes as mentioned in Table 2.4.2-1 of SW GD. Late applications are only defined up to BBCH 89. However, post-harvest application are made between BBCH 90 and 99, from 50% leaf falling till after leaf falling (autumn). Therefore, in line with groundwater risk assessment, the same drift as an early application should be applied. Consequently, RMS considers that pome/stone fruit early applications FOCUS SW crop should be selected for modelling post-harvest uses.

### Risk refinements (STEP 4)

Risk refinements based on FOCUS STEP 4 calculations of all scenarios of all intended uses were presented at Vol 3CP B9.4. Single applications led the worst-case PEC<sub>sw</sub> values respect to multiple applications. Then, as conservative approach, only the PEC/RAC results from this application patten was considered for the selection of the mitigation measures at FOCUS STEP 4. In this sense, the following conclusions were reached:

- For the intended used in **Apple/pear** ( $2 \times 0.68$  kg a.s./ha):

  - **Early applications:** no unacceptable risk for aquatic organisms can be concluded for:
    - when ETO-RAC is considered: scenarios D4 pond, D5 pond and R1 pond applying 20 m no-spray buffer zone + 90% drift reduction or 50 m no-spray buffer zone.
    - When ERO-RAC is applied: scenarios D4 pond, D5 pond and R1 pond applying 25 m no-spray buffer zone. All scenarios if 20 m no-spray buffer zone + 90% drift reduction or 50 m no-spray buffer zone are implemented.
  - **Late applications:** no unacceptable risk for aquatic organisms can be concluded for:
    - when ETO-RAC is considered: scenarios D4 pond, D5 pond and R1 pond applying 25 m no-spray buffer zone. Scenarios R1 stream and R4 stream applying 50 m no-spray buffer zone. All scenarios if 20 m no-spray buffer zone + 90% drift reduction are implemented.
    - When ERO-RAC is applied: all scenarios applying 25 m no-spray buffer zone or 20 m no-spray buffer zone + 90% drift reduction.

- For the intended used in **Cherry** ( $2 \times 0.68$  kg a.s./ha):

  - **Summer applications:** no unacceptable risk for aquatic organisms can be concluded for:
    - when ETO-RAC is considered: scenarios D4 pond, D5 pond and R1 pond applying 25 m no-spray. Scenarios R1 stream and R4 stream applying 50 m no-spray buffer zone. All scenarios if 20 m no-spray buffer zone + 90% drift reduction are implemented.
    - When ERO-RAC is applied: all scenarios if 25 m no-spray buffer zone or 20 m no-spray buffer zone + 90% drift reduction are implemented.
  - **Late applications:** no unacceptable risk for aquatic organisms can be concluded for:
    - when ETO-RAC is considered: scenarios D4 pond, D5 pond and R1 pond applying 25 m no-spray buffer zone. Scenarios R1 stream and R4 stream applying 50 m no-spray buffer zone. All scenarios if 20 m no-spray buffer zone + 90% drift reduction are implemented.
    - When ERO-RAC is applied: all scenarios applying 25 m no-spray buffer zone or 20 m no-spray buffer zone + 90% drift reduction.
  - **Post-harvest applications:** no unacceptable risk for aquatic organisms can be concluded for:
    - when ETO-RAC is considered: scenarios D4 pond, D5 pond and R1 pond applying 50 m no-spray buffer zone or 20 m no-spray buffer zone + 90% drift reduction are implemented.

RMS noted that the recovery option for refining the risk is not an adequate approach for post-harvest applications.

- For the intended used in **Peach** ( $2 \times 0.9$  kg a.s./ha):

  - **Early applications:** no unacceptable risk for aquatic organisms can be concluded for:
    - when ETO-RAC is considered: scenarios D4 pond, D5 pond and R1 pond applying 20 m no-spray buffer zone + 90% drift reduction 50 m no-spray buffer zone.
    - When ERO-RAC is applied: scenarios D4 pond, D5 pond and R1 pond applying 25 m no-spray buffer zone. All scenarios if 20 m no-spray buffer zone + 90% drift reduction are implemented.
  - **Late applications:** no unacceptable risk for aquatic organisms can be concluded for:
    - when ETO-RAC is considered: scenarios D4 pond, D5 pond and R1 pond applying 25 m no-spray buffer zone. All scenarios if 20 m no-spray buffer zone + 90% drift reduction are implemented.

- When ERO-RAC is applied: all scenarios applying 25 m no-spray buffer zone or 20 m no-spray buffer zone + 90% drift reduction.
- o **Post-harvest applications:** no unacceptable risk for aquatic organisms can be concluded for:
  - when ETO-RAC is considered: scenarios D4 pond, D5 pond and R1 pond applying 20 m no-spray buffer zone + 90% drift reduction 50 m no-spray buffer zone.

RMS noted that the recovery option for refining the risk is not an adequate approach for post-harvest applications.

The risk mitigation measures consisting in « 50 m no-spray buffer zone » or « 20 m no-spray buffer zone + 90% drift reduction » are beyond the 95% limit recommended by the FOCUS landscape and mitigation guidance (FOCUS, 2007; SANCO/10422/2005, version 2.0, September 2007). For these mitigation measures, **supporting evidence of their efficacy reducing drift should be provided. The applicability of each particular mitigation measures should be assessed at the Member State level.**

#### Evaluation of exposure profiles

However, before a definitive conclusion on the risk acceptability can be drawn, there is a need to consider whether the exposure profiles in the mesocosm study of ██████████ (2021b) are broadly comparable to those predicted in the field. The exposure pattern in the mesocosm study was compared with FOCUS exposure profile predictions to verify whether the mesocosm study is a realistic worst case in terms of exposure of the representative uses (i.e. application to apple/pear, cherry or peach). In this sense, a visual assessment of the overlaying graphs was performed based on envelope curve concept for the exposure scenarios where PEC<sub>sw</sub>(at FOCUS Step 3 or Step 4)/RAC were <1 (safe use). After visual assessment, not all simulated events were covered by the exposure profile of the mesocosms, then higher risk mitigation measures were proposed by the RMS (see overall conclusion table below). For pond scenarios D4p, D5p and R1p for FOCUS step 3 (analysis based on ERO) and step 4 considering 25 m BZ (analysis based on ETO) risk mitigation measures were proposed by the RMS in order to obtain maximum PEC<sub>sw</sub> values below Tier 1-RAC. For R4s scenarios, peaks of runoff were not covered by the mesocosm exposure profile when ETO-RAC is considered, consequently, a 20 m of vegetated filter strip zone was applied to these scenarios.

Nevertheless, it was concluded that the mesocosm study showed an exposure profile similar to that shown by initial predicted concentrations from the FOCUS modelling, characterized by an initial peak following spray drift and a rapid decline in the water phase. Therefore, the exposure regime tested in the mesocosms is more or less realistic to worst case relative to the predicted exposure profiles for the different FOCUS scenarios.

Moreover, the exposure period above the ETO-RAC and the time needed for recovery were assessed, as it is also necessary to demonstrate that an acceptable time-course for recovery within 8 weeks can be expected to demonstrate an acceptable risk using the ERO-RAC (protection goal according EFSA 2013 Guidance). The duration of the potential total effect period of each scenario, considering the recovery period determined in the mesocosm study of ██████████ (2021b) for the most sensitive population (3 weeks after the second application for *Chroomonas acuta*) were checked. EPAT analyses were run for scenarios where there were exceedances of ETO-RAC, but PEC<sub>sw</sub> (at FOCUS Step 4)/RAC were <1 considering ERO-RAC. The exposure period above the ETO-RAC, for the corresponding exposure scenario assessed, was shorter than the time needed for recovery derived from the mesocosms (see Vol 3CP B9.4.4 for further details). Therefore, the provisional ERO-RAC can be considered as a **definitive ERO-RAC**.

After the risk assessment based on exposure profiles, the risk for aquatic organisms after a two-fold application of Dodine 544 SC on apples/pear, cherry and peach can be considered acceptable if the mitigation measures reported in the following table are implemented. Unacceptable risk for aquatic organisms was identified for post-harvest applications on cherry and peach.

**Table 2.9.9.2-10. Overview of risk mitigation measures required for each relevant exposure scenario following a two-fold application of Dodine 544 SC on apples/pear, cherry and peach.**

| Intended use                         | Exposure scenario   |                                 |                                  |                                 |                                  |                                 |                                  |                                  |                                  |                                  |   |

NSB: no-spray buffer zone, DRN: drift reduction/drift reducing nozzles

\*mitigation measures derived from the use of ERO-RAC=2.5 µg/L.

Note: FOCUS Step 4 calculations with spray drift mitigations have been performed for all the representative uses. FOCUS landscape and mitigation guidance advises that the maximum acceptable reduction in spray drift using any combination of mitigation techniques is 95%. For the proposed uses considered in the Step 4 calculations, when possible, two options are presented, one based on mitigations according to FOCUS L&M GD (2007) and other based on mitigations greater than the ceiling of 95%. **Applicant is requested to demonstrate that a drift reduction above 95% is possible under the proposed conditions of use.** Moreover, the choice, combination and appropriateness of available mitigation measures (e.g. drift-reducing nozzles, (vegetated) buffers etc.) should finally be decided at member state level.

**2.9.9.3 Summary of risk assessment for bees**

The evaluation of the risk for bees was performed in accordance with the recommendations of EFSA (2013)<sup>8</sup>, although the guidance document is not yet approved, and certain parts are currently under revision. No risk assessment for bumble bees and solitary bees is performed as recommended in EFSA (2015)<sup>9</sup>. Toxicity endpoints from available studies for honey bees are summarized in the **Table 2.9.3.1-1**.

The acute risk to honeybees by oral and contact exposure following all representative uses of Dodine 544 SC in orchards was calculated to be acceptable at screening level.

The chronic risk to adult honeybees following all representative uses of Dodine 544 SC in orchards was calculated to be unacceptable at Tier 1 for all relevant exposure scenarios except for the treated crop scenario at BBCH ≥ 70. The chronic risk to honeybee larvae following the representative uses in apples/pear and cherry was calculated to be unacceptable at Tier 1 for all relevant exposure scenarios except for the treated crop scenario at BBCH 10-19, BBCH 20-39 and BCH 40-69 and the weeds scenario at BBCH < 10. For the intended uses in peach, the chronic risk to honeybee larvae is calculated to be unacceptable at Tier 1 for all relevant exposure scenarios except for the treated crop scenario at BBCH 10-19, BBCH 20-39 and BCH 40-69 and the weeds scenario at BBCH < 10 and BBCH 10-19.

An indicative risk assessment was also performed for bumblebees and solitary bees by RMS, by means of an assessment factor of 10 to extrapolate from honeybee endpoints to endpoints for bumblebees and solitary bees.

At Tier 1, acute and chronic risk cannot be excluded for both bumblebees and solitary bees.

**Risk assessment for apples/pear and cherry at 2 × 680 g a.s./ha**

**According to EFSA Guidance 3295, 2013, risk to honeybees, bumblebees and solitary bees cannot be excluded at Tier 1.**

Dodine posing a low risk to honeybees in laboratory studies, however chronic bee assessment in accordance with EFSA Journal 2013: 11(7):3295 suggest that further investigations are needed (ETR values were above the relevant triggers).

To address the risk on bees, two semi-field studies were submitted to ensure no effects to the whole colony would be overlooked. The semi-field studies were conducted in the central and in the southern zone according to OECD 75.

The purpose of both studies was to determine the potential effects of Dodine 544 SC on the honeybee (*Apis mellifera*) after two foliar applications at 900 g a.s./ha in a 7-day interval on flowering Phacelia (*Phacelia tanacetifolia*) under semi-field conditions and exposure of bees. Special attention was paid to detailed brood development via photo documentation of initially labelled eggs representing the main endpoint. Further major endpoints were the mortality, foraging activity, bee behavior and the colony and brood development. Additionally, residues of Dodine were determined in flowers, pollen, and nectar.

Overall, no adverse effects on honey bee brood or honey bee colony survival were observed. Effects on mortality were observed for the exposure period in the Germany trial when the application was done during the bee flight, however for the overall exposure there were not any significant effect between test items and control. **Mitigation measures could be proposed to avoid the effects on mortality observed during the exposure period. i.e to protect bees and other pollinating insects do not use where bees are actively foraging.**

Regarding the risk from exposure to contaminated water, an acceptable risk to honeybees by oral exposure to contaminated surface water and contaminated water in puddles was calculated following all representative uses of Dodine 544 SC in orchards. Although the calculated screening ETR values indicate a potential chronic risk for adult honeybees and honeybee larvae exposed to contaminated guttation water, no accumulation of Dodine in guttation fluids and subsequent exposure of honeybees to guttation water is expected.

The sub-lethal effects were described and reported in each laboratory study as well as in any higher-tier study. In the semi-field studies, the application and subsequent exposure of bees to the test item I, test item II, respectively, did not result in behaviour abnormalities compared to the bees in the control group. No symptoms of apathy, intoxication or any deviations to the normal behaviour of bees occurred. Information about the development of hypopharyngeal glands has not been provided.

Finally, applicant has stated that there are no indications that dodine has accumulative potential. However, **a justification in line with section 8.1.1.3 and pertinent part of Appendix O of EFSA GD (2013) should be provided.**

**2.9.9.4 Summary of risk assessment for non-target arthropods**

The evaluation of the risk for non-target arthropods has been performed in accordance with the recommendations of the “Guidance Document on Terrestrial Ecotoxicology”, and in consideration of the recommendations of the guidance document ESCORT 2.

Two laboratory (glass plates) tests on the effects of dodine on non-target arthropods *T. pyri* and *A. rhopalosiphi* were submitted with dodine formulated as 400 g/L SC (Syllit 400 SC). These studies were already evaluated and accepted for the Annex I inclusion. In addition, two new studies have been conducted using the formulation Dodine 544 SC for the purpose of renewal of the approval of Dodine.

Extended laboratory tests were also available with the Annex I inclusion formulation (Syllit 400 SC). In total, five studies on natural substrates investigating the effects of Dodine to the standard specie *Typhlodromus pyri* as well as to additional arthropod species (i.e., *Coccinella septempunctata*, *Orius insidiosus*, *Chrysoperla carnea*).

Since new data with the current formulation are available, the applicant has only considered the results of these new studies at first-tier for the risk assessment. Since all HQ values were below the trigger value, further assessment using higher tier data was not conducted.

However, higher mortality for *Typhlodromus pyri* was observed using the previous formulation. Therefore, the risk assessment has been repeated by RMS considering the endpoint derived from ██████████ (1997b) expressed in grams of dodine/ha. Additionally, since an extended laboratory study was available for *Typhlodromus pyri*, higher tier risk assessment has been carried out as well.

The summary of the risk assessment is included below:

**First tier risk assessment (glass plate studies)**

Data from the initial laboratory studies on inert substrate with *T. pyri* and *A. rhopalosiphi*. were used. The in-field risk assessment is presented below:

**Table 2.9.9.4-1: First-tier assessment of the in-field risk for non-target arthropods due to the use of Dodine 544 SC in apples/pear and cherry (2x 680 g a.s./ha)**

|                                     |                              |                        |               |                               |

|                                     | <i>Aphidius rhopalosiphi</i> | > 1530                 |               | 1.11                          |

MAF: Multiple application factor; PER: Predicted environmental rate; HQ: Hazard quotient. Criteria values shown in bold breach the relevant trigger.

The in-field HQs at Tier I for the standard laboratory species *Aphidius rhopalosiphi* and *Typhlodromus pyri* are below the trigger value of 2, indicating that risk to non-target arthropods is low in in-field areas following the application of Dodine 544 SC according to the proposed use pattern in apples/pear, cherry and peach.

### Risk assessment for off-field exposure

A default correction factor of 10, to account for uncertainty with the extrapolation from *Typhlodromus pyri* and *Aphidius rhopalosiphi* as indicator species to all off-field non-target arthropods was used in HQ calculations. Moreover, a VDF of 5 was used as recommended in the Outcome of the Pesticides Peer Review Meeting on general recurring issues in ecotoxicology (EFSA Supporting publication 2019:EN-1673).

**Table 2.9.9.4-3: First-tier assessment of the off-field risk for non-target arthropods due to the use of Dodine 544 SC in apples/pear and cherry (2x 680 g a.s./ha)**

MAF: Multiple application factor; vdf: Vegetation distribution factor; (corr.) PER: (corrected) Predicted environmental rate; CF: Correction factor; HQ: Hazard quotient. Criteria values shown in bold breach the relevant trigger.

The off-field HQs at Tier I for the standard laboratory species *Aphidius rhopalosiphi* and *Typhlodromus pyri* are below the trigger value of 2, indicating that risk to non-target arthropods is low in off-field areas following the application of Dodine 544 SC according to the proposed use pattern in apples/pear, cherry and peach.

### Tier 2 risk assessment (extended laboratory studies)

HQ approach is not adequate for Tier 2. At higher tier a trigger value for lethal or sub-lethal effects of 50% after exposure of the test organisms to fresh or aged residues of plant protection products was set in ESCORT 2.

The maximum PER<sub>in-field</sub> and off-field values resulted from application of Dodine 544 SC to peach. So these values are used in the Tier II risk assessment as they are protective of all intended uses.

**Table 2.9.9.4-5: In-field risk assessment for non-target arthropods (Tier 2) exposed to Dodine 544 SC.**

|                              |               |

|                              | <i>Coccinella septempunctata</i> | 1800                         | 1800                         | 87.31                            | Yes                                      |
|                              | <i>Orius insidiosus</i>          | 1800                         | -                            | 87.31                            | Yes                                      |
|                              | <i>Chrysoperla carnea</i>        | 1800                         | -                            | 87.31                            | Yes                                      |

<sup>1</sup> Drift rate (higher tier) = application rate \* MAF \* (drift factor/vegetation distribution factor)\* correction factor

The extended laboratory studies showed no unacceptable effect on reproduction and mortality up to the maximum application rate of 2x900 g a.s./ha (mortality and reproductive effects were below 50 %).

The active substance Dodine belongs to the family of guanidine. According to FRAC (Fungicide resistance action committee), it is classified as U12, an unknown mode of action. The proposed target site of Dodine is the disruption of cellular membranes.

Based on the above, the risk for non-target arthropods is acceptable for all proposed used, no further investigation are necessary in semi-field or field scenarios.

### 2.9.9.5 Summary of risk assessment for non-target soil meso- and macrofauna

#### 2.9.9.5.1 Risk assessment for earthworms

The effects of Dodine (technical or formulated) to earthworms under both acute and long-term exposure conditions are adequately presented and discussed in Volume 3 CA B.9 Point 9.4.1. and Volume 3 CP B.9 Point 9.7.1. Considering the available, complete data set, the worst-case EC<sub>10</sub> of 62.4 mg a.s./kg dw is proposed for use in the long-term risk assessment for earthworms. This endpoint is provisional pending on the submission of the statistical re-evaluation of [REDACTED] 2007 (KCP 10.4.1.1/01).

Based on the results of the soil degradation studies, there is no Dodine metabolite found in soil at proportions > 10% AR, 5% AR in two consecutive samples and/or >5% at the end of the study. Thus Dodine is the only compound to be further considered regarding its toxicity to soil organisms.

The evaluation of the risk for earthworms is performed in accordance with the recommendations of the “Guidance Document on Terrestrial Ecotoxicology”, as provided by the Commission Services (SANCO/10329/2002 rev 2 (final), October 17, 2002). The potential long-term risk of Dodine to earthworms is assessed by calculating long-term Toxicity Exposure Ratios (TER<sub>LT</sub> values), by comparing the NOEC/EC<sub>10</sub> values and the maximum PEC<sub>soil</sub> according to the following equation:

$$TER_{LT} = \frac{NOEC \text{ (mg/kg)}}{PEC_s \text{ (mg/kg)}}$$

The resulting TER<sub>LT</sub> value is presented in **Table 2.9.9.5.1-1** below.

**Table 2.9.9.5.1-1 First-tier assessment of the chronic risk for earthworms due to the use of Dodine 544 SC in peach (early application) <sup>a</sup>**

|                                      |  |   |   |
|--------------------------------------|--|---|---|
| <b>Intended use</b>                  | Peach (early application), 2 × 0.9 kg a.s./ha, 21-day interval |   |   |
| <b>Chronic effects on earthworms</b> |  |   |   |
| <b>Product/active substance</b>      | <b>EC<sub>10</sub><br/>[mg a.s./kg dw]</b>                     | <b>PEC<sub>soil</sub><br/>[mg a.s./kg dw]</b> | <b>TER<sub>LT</sub><br/>(criterion TER ≥ 5)</b> |
| Dodine                               | 62.4*  | 0.746   | 83.64   |

<sup>a</sup> The PEC<sub>soil</sub> values calculated for the early application in peach represent a worst-case, thus cover also all other intended uses of Dodine 544 SC in orchards

\* The EC<sub>10</sub> = 62.4 mg a.s./kg dw is considered provisional pending on the submission of the statistical re-evaluation of [REDACTED] 2007 (KCP 10.4.1.1/01).

The long-term TER value for Dodine meet the trigger value of 5, indicating no unacceptable long-term risk to earthworms following the intended uses of Dodine 544 SC in orchards.

#### 2.9.9.5.2 Risk assessment for non-target soil meso- and macrofauna (other than earthworms)

The effects of Dodine formulated as Dodine 544 SC on the survival and reproductive performance of non-target soil meso- and macrofauna (other than earthworms) is adequately presented and discussed in Volume 3 CP B9, Point B.9.7.2. Considering the available data, the NOEC of 1000 mg a.s./kg dw is proposed for use in the risk assessment for *Hypoaspis aculeifer* and the NOEC endpoints of 3.2 and 541.7 mg a.s./kg dw are proposed for use in the Tier 1 and refined tier risk assessment, respectively for *Folsomia candida*. All LogPow values of dodine were < 2, hence correction of the endpoints are not needed.

Based on the results of the soil degradation studies, there is no Dodine metabolite found in soil at proportions > 10% AR and thus Dodine is the only compound to be further considered regarding its toxicity to soil organisms.

The evaluation of the risk for soil meso- and macrofauna (other than earthworms) is performed in accordance with the recommendations of the “Guidance Document on Terrestrial Ecotoxicology”, as provided by the Commission Services (SANCO/10329/2002 rev 2 (final), October 17, 2002). The potential long-term risk of Dodine to for soil meso- and macrofauna (other than earthworms) is assessed by calculating long-term Toxicity Exposure Ratios (TER<sub>LT</sub> values), by comparing the NOEC values and the maximum PEC<sub>soil</sub>.

The resulting TER<sub>LT</sub> values are presented in **Table 2.9.9.5.2-1** below.

**Table 2.9.9.5.2-1 First-tier assessment of the chronic risk for soil meso- and macrofauna (other than earthworms) due to the use of Dodine 544 SC**

| <b>Chronic effects on <i>Hypoaspis aculeifer</i></b>            |                                      |                            |  |   |
|---|--------------------------------------|----------------------------|--|---|
| <b>Intended use</b>   | <b>Product/<br/>active substance</b> | <b>NOEC<br/>[mg/kg dw]</b> | <b>PEC<sub>Soil</sub><br/>[mg/kg dw]</b> | <b>TER<sub>LT</sub><br/>(criterion<br/>TER ≥ 5)</b> |
| Pome/pear (BBCH 01),<br>2 × 0.68 kg a.s./ha,<br>21-day interval | Dodine                               | 1000                       | 0.646                                    | 1548  |
| Cherry (BBCH 60),<br>2 × 0.68 kg a.s./ha,<br>21-day interval    | Dodine                               | 1000                       | 0.517                                    | 1934  |

| <b>Chronic effects on <i>Folsomia candida</i></b>               |                                      |                            |  |   |
| <b>Intended use</b>   | <b>Product/<br/>active substance</b> | <b>NOEC<br/>[mg/kg dw]</b> | <b>PEC<sub>Soil</sub><br/>[mg/kg dw]</b> | <b>TER<sub>LT</sub><br/>(criterion<br/>TER ≥ 5)</b> |
| Pome/pear (BBCH 01),<br>2 × 0.68 kg a.s./ha,<br>21-day interval | Dodine                               | 3.2                        | 0.646                                    | <b>4.9</b>  |
| Cherry (BBCH 60),<br>2 × 0.68 kg a.s./ha,<br>21-day interval    | Dodine                               | 3.2                        | 0.517                                    | 6.2   |
| Peach (BBCH 01),<br>2 × 0.9 kg a.s./ha,<br>21-day interval      | Dodine                               | 3.2                        | 0.746                                    | <b>4.3</b>  |

<sup>a</sup> The PEC<sub>soil</sub> values calculated for the early application in peach represent a worst-case, thus cover also all other intended uses of Dodine 544 SC in orchards  
TER values shown in bold fall below the relevant trigger

The tier 1 risk assessment, indicated a high risk for *Folsomia candida* after early applications of dodine on peach. To refine the risk assessment for such uses, one toxicity test with *Folsomia candida* conducted in a natural soil was available.

To date, only two refinement options are available in the current SANCO guidance document (2002): to use of natural soils in laboratory toxicity test or to conduct higher-tier assessment with field studies. Moreover, it is stated that the type of the organic matter influences sorption and hence bioavailability. Therefore, a standardised arable soil closer to the scenarios in the exposure assessment would be preferred over the OECD artificial soil. Please, refer to Scientific opinion addressing the state of the science on risk assessment of plant protection products for in-soil organisms (EFSA, 2017).

Nevertheless, currently there is no guidance on what natural soil properties would be considered acceptable. Some indications were provided in [REDACTED] (2011<sup>10</sup>).

Co-RMS refers to the results of two reports, [REDACTED] (2017<sup>11</sup>) and [REDACTED] (2017<sup>12</sup>), to support the conclusion reached during 4th central zone harmonisation meeting in 2018 on not using natural soils for the risk assessment as long as no further results from ongoing research projects are available. These reports are not available to RMS and without further details about test design, investigated endpoints, exposure conditions, and sensitivity analysis performed, it is difficult to understand the reasoning behind.

We agree with co-RMS that FOCUS SW scenarios are not relevant for PECsoil calculations, not being appropriate to compare soil properties of LUFA Speyer 2.2 with FOCUS sw scenarios in order to justify its representativeness. However, this soil is commonly used in aerobic degradation test as representative of EU agricultural soils, with soil properties within the recommended ranges of OECD 307 guideline.

Moreover, the LUFA 2.2 soil is on the spectrum of lower organic matter, clay and pH compared to OECD 232 artificial soil. Data on adsorption in four soils suggested that sorption is lower in acid soil compared to basic soils. Therefore, it is expected a higher bioavailability of dodine in LUFA 2.2 soil.

| Name                     | Texture    | Organic matter (%) | Clay % | Silt % | Sand % | WHC max | pH                        |
|--------------------------|------------|--------------------|--------|--------|--------|---------|---------------------------|
| Artificial soil OECD 232 | -          | 5                  | 20     | 6      | 74     | 45      | 6 (in CaCl <sub>2</sub> ) |
| Lufa Speyer 2.2          | Loamy sand | 3.14               | 6.7    | 13.2   | 77.1   | 49.76   | 5.3 (in H <sub>2</sub> O) |

Finally, it is highlighted that the validity criteria of OECD 232 were met and the study is considered acceptable.

Artificial soils do not necessarily reflect the behaviour of chemicals in the environment. In general, the exposure and toxicity of the Plant Protection Products for in-soil organisms in natural agro-ecosystems is influenced by the fate of a substance and their bioavailability in the habitat soil. This bioavailability is influenced by a multitude of factors. Consequently, the use of only one natural soil without a proper sensitivity analysis for a comparison of test performed in other natural soils is highly uncertain and may result in the risk assessment being under-protective. Taking into account that the study is reliable, RMS has proposed to use it as part of a Weight of Evidence approach.

All in all, RMS has concluded that the long-term risk to soil meso- and macrofauna (other than earthworms) can be considered acceptable following the application of Dodine 544 SC in orchards based on the available data:

- 1.- Dodine exhibits low persistence in soil (normalized geometric mean DT<sub>50</sub> of 5.25 days) with low potential to bioaccumulation (log Pow < 2).
- 2.- An acceptable risk is indicated based on the Tier 1 EC<sub>10</sub> for *Folsomia* of 6.6 mg as/kg dw. The TER<sub>LT</sub> value of 10.2 and 8.8 for the uses on pome/pear and peach, respectively.
- 3.- An acceptable risk is indicated based on the Tier 2 results of the *Folsomia* study performed using an environmentally relevant substrate (i.e. natural soil). Taking into account a NOEC of 541.7 mg a.s./kg dw TER<sub>LT</sub> for *Folsomia candida* is above the Annex VI trigger of 5, with a high safety margin, indicating an acceptable risk to soil macro-organisms.

4.- Tier 1 risk assessment of standard test species of non-target arthropods, *A. rhopalosiphi* and *T. pyri*, indicated a low risk based on glass plate studies. Moreover, Tier 2 risk assessment based on extended laboratory studies (toxicity of dodine to NTA on natural substrates) on four species of NTA indicated a low risk also.

#### 2.9.9.6. Risk assessment for soil nitrogen transformation

The effects of Dodine formulated as Dodine 400 SC on soil microbial activity (nitrogen turnover and short-time respiration) are adequately presented and discussed in Volume 3 CP Point B.9.9. The maximum tested concentration with lower than 25% effects on nitrogen transformation compared to the control, i.e., 12 mg a.s./kg dw, is used in the risk assessment. The results of the study are considered as supportive information. **A data gap has been set to the applicant to submit the soil nitrogen transformation rate expressed in mg nitrate/kg dry weight soil/day between each measurement day for control and all tested concentrations in order to determine the difference in transformation rates as recommended by the OECD 216.**

Based on the results of the soil degradation studies, there is no Dodine metabolite found in soil at proportions > 10% AR, 5% at two consecutive samplings and/or >5% at the end of the study. Therefore, Dodine is the only compound to be further considered regarding its toxicity to soil organisms.

The evaluation of the risk for soil microorganisms is performed in accordance with the recommendations of the “Guidance Document on Terrestrial Ecotoxicology”, as provided by the Commission Services (SANCO/10329/2002 rev 2 (final), October 17, 2002). The risk to soil microorganisms was evaluated by comparing the concentration resulting in ≤ 25% effects on nitrogen transformation compared to the control, as derived from the available laboratory test, with the maximum  $PEC_{\text{Soil, ini}}$  value calculated for Dodine (please, refer to Volume 3 CP B8 Point B.8.2). The results of the comparison expressed as Margin of Safety (MoS) are presented in **Table 2.9.9.6-1** below.

**Table 2.9.9.6-1 Assessment of the risk for effects on soil microorganisms due to the use of Dodine 544 SC in peach (early application) <sup>a</sup>**

| Intended use             | Peach (early application), 2 × 0.9 kg a.s./ha, 21-day interval |  |                  |
|--------------------------|--|--|------------------|
| N-mineralization         |  |  |                  |
| Product/active substance | Max. conc. with effects ≤ 25% [mg a.s./kg dw]                  | $PEC_{\text{initial, Soil}}$ [mg a.s./kg dw] | Margin of safety |
| Dodine                   | 12*  | 0.746  | 16               |

<sup>a</sup> The  $PEC_{\text{initial, soil}}$  value calculated for the early application in peach represents a worst-case, thus covers also all other intended uses of Dodine 544 SC in orchards

\* Results of the study are provisional (see data gap above)

Based on the results of the risk assessment no unacceptable effects on soil microbial activity are expected following application of Dodine 544 SC according to the proposed use pattern.

#### 2.9.9.6. Risk assessment for terrestrial non-target plants

The effects of Dodine (technical and formulated) to terrestrial non-target higher plants are adequately presented and discussed in Volume 3 CA B9 Point 9.6 and Volume 3 CP B9 Point B.9.11. The EU agreed  $ER_{50} > 2.9$  kg a.s./ha for Dodine for both seedling emergence and vegetative vigour is retained in the risk assessment for non-target terrestrial plants.

The formulated product Dodine 544 SC is not an herbicide, following data requirement Commission Regulation (EU) 284/2013 the effects of Dodine 544 SC can be adequately predicted based on active substance data.

The evaluation of the risk for terrestrial non-target higher plants is performed in accordance with the recommendations of the “Guidance Document on Terrestrial Ecotoxicology”, (SANCO/10329/2002 rev.2 final, 2002). It is restricted to off-field situations where spray drift will be the main route of exposure, as non-target plants are non-crop plants located outside the treated area.

The results of the risk assessment for terrestrial non-target plants are shown in **Tables 2.9.9.6-1** and **2.9.9.6-2** below.

**Table 2.9.9.6-1 Assessment of the risk for non-target plants due to the use of Dodine 544 SC in apples/pear and cherry**

|                                 |                                    |                   |  |                                   |
|---------------------------------|------------------------------------|-------------------|--|-----------------------------------|
| <b>Intended use</b>             | Apples/pear, cherry                |                   |  |                                   |
| <b>Active substance/product</b> | Dodine/Dodine 544 SC               |                   |  |                                   |
| <b>Application rate [kg/ha]</b> | 2 × 0.68                           |                   |  |                                   |
| <b>Test species</b>             | <b>ER<sub>50</sub><br/>[kg/ha]</b> | <b>Drift rate</b> | <b>PER<sub>off-field</sub><br/>[kg/ha]</b> | <b>TER criterion:<br/>TER ≥ 5</b> |
| Vegetative vigour               | > 2.9                              | 0.292             | 0.199                                      | > 14.6                            |
| Seedling emergence              | > 2.9                              | 0.292             | 0.199                                      | > 14.6                            |

PER: Predicted environmental rate; TER: toxicity to exposure ratio. TER values shown in bold fall below the relevant trigger.

| <b>Intended use</b>             | Peach                              |                   |  |                                   |
| <b>Active substance/product</b> | Dodine/Dodine 544 SC               |                   |  |                                   |
| <b>Application rate [kg/ha]</b> | 2 × 0.9                            |                   |  |                                   |
| <b>Test species</b>             | <b>ER<sub>50</sub><br/>[kg/ha]</b> | <b>Drift rate</b> | <b>PER<sub>off-field</sub><br/>[kg/ha]</b> | <b>TER criterion:<br/>TER ≥ 5</b> |
| Vegetative vigour               | > 2.9                              | 0.292             | 0.263                                      | > 11.0                            |
| Seedling emergence              | > 2.9                              | 0.292             | 0.263                                      | > 11.0                            |

PER: Predicted environmental rate; TER: toxicity to exposure ratio. TER values shown in bold fall below the relevant trigger.

The calculated TER values are above the trigger of 5, indicating an acceptable risk for non-target terrestrial plants following application of Dodine 544 SC according to the proposed use pattern.

## 2.10 ENDOCRINE DISRUPTING PROPERTIES

### 2.10.1 ED assessment for humans

#### 2.10.1.1. Gather all relevant information

The studies included in the volume 3 B.6 of this RAR provided the information used for this assessment, specifically, short-term toxicity studies, long-term toxicity and carcinogenicity studies, reproductive toxicity studies, immunotoxicity studies and studies on endocrine disruption (*in silico*, *in vitro* mechanistic and *in vivo* mechanistic) (Table 2.10.1.1).

Data were populated in the Excel template provided as *Appendix E* to the *EFSA/ECHA guidance for the identification of endocrine disruptors* (2018). According to this template, each study was given a number (Study ID Matrix) for its identification in the data-matrix of the Excel.

2.10.1.2. ED assessment for T-modality

2.10.1.2.1. Dataset sufficiency in T-mediated parameters

|                              | Sufficiently investigated   |
|------------------------------|---|
| <b>T-mediated parameters</b> | Yes, based on the availability of the following studies:<br>- Two repeated dose 28-day oral toxicity studies in rodents (OECD TG 407) <sup>a, b</sup><br>- One repeated dose 90-day oral toxicity studies in rodents (OECD TG 408) <sup>a, b</sup><br>- A repeated dose 90-day oral toxicity study in non-rodents (OECD TG 409) <sup>a, b</sup><br>- A 52-week oral toxicity study in non-rodents (OECD TG 452) <sup>b</sup><br>- A 1-year oral toxicity study in non-rodents (OECD TG 452) <sup>a, b</sup><br>- A long-term repeated dose toxicity and carcinogenicity study (OECD TG 453) <sup>a, b</sup><br>- A long-term repeated dose toxicity and carcinogenicity study (OECD TG 453) <sup>b</sup><br>- Developmental toxicity studies in rats and rabbits (OECD TG 414)<br>- A two-generation reproduction toxicity test (OECD TG 416) |

<sup>a</sup> Thyroid weight measured. <sup>b</sup> Thyroid histopathology measured.

The repeated dose 28-day oral toxicity studies (OECD TG 407), the repeated dose 90-day oral toxicity studies in rodents (OECD TG 408), the two-generation reproduction toxicity test (OECD TG 416) and the developmental toxicity studies in rats and rabbits (OECD TG 414) were conducted according to outdated versions of the OECD test guidelines, and consequently, some T-mediated parameters have not been measured.

The long-term repeated dose toxicity and carcinogenicity study in rats (OECD TG 453) was conducted according an outdated version of the guideline, however all the recommended T-mediated parameters in the current guideline were measured.

The repeated dose 90-day oral toxicity study in non-rodents (OECD TG 409) was performed according to the last and updated OECD test guidelines.

The T-mediated parameters that have not been measured in the studies are indicated in table 2.10.1.2.1.

**Table 2.10.1.2.1: T-mediated parameters not measured**

|   |   |
|---|---|
| <b>OECD TG 407 - T-mediated parameters not investigated</b> |   |
| - T3 and/or T4 level  | - Thyroid stimulating hormone level (TSH) |
| <b>OECD TG 408 - T-mediated parameters not investigated</b> |   |
| - T3 and/or T4 level  | - Low-density lipoproteins (LDL)          |
| - Thyroid stimulating hormone level (TSH)                   | - High-density lipoproteins (HDL)         |
| <b>OECD TG 452 - T-mediated parameters not investigated</b> |   |
| - Thyroid weight  |   |

| <b>OECD TG 414 - T-mediated parameters not investigated</b> |   |
|---|---|
| - Thyroid weight  | - T3 and/or T4 level                      |
| - Thyroid histopathology                                    | - Thyroid stimulating hormone level (TSH) |
| <b>OECD TG 416 - T-mediated parameters not investigated</b> |   |
| - Thyroid weight  |   |

However, it is considered that T-mediated parameters have been sufficiently investigated taking into account the following points:

- The thyroid histopathology has been measured in eleven studies: OECD TG 407 (B.6.3.1.1, ID: 32 and B.6.3.1.2, ID: 33), 6-week repeat dose toxicity study in dogs (B.6.3.1.6, ID: 41, no guideline), OECD TG 408 in rats (B.6.3.2.1, ID: 38), OECD TG 408 in mice (B.6.3.2.4, ID: 39), OECD TG 409 (B.6.3.2.5, ID: 40), OECD TG 452 in dogs (B.6.3.3.1, ID: 47 and B.6.3.3.2, ID: 45), OECD TG 410 (B.6.3.4.1.1, ID: 36), OECD TG 453 in rats and mice (B.6.5.1, ID: 48 and B.6.5.2, ID: 49).
- The thyroid weight has been measured in seven studies: OECD TG 407 (B.6.3.1.1, ID: 32 and B.6.3.1.2, ID: 33), 6-week repeat dose toxicity study in dogs (B.6.3.1.6, ID: 41, no guideline), OECD TG 408 (B.6.3.2.1, ID: 38), OECD TG 409 (B.6.3.2.5, ID: 40), OECD TG 452 in dogs (B.6.3.3.2, ID: 45) and OECD TG 453 (B.6.5.1, ID: 48).
- The thyroid hormones (T3 and T4) levels have been measured only in one study: OECD TG 441 (B.6.8.3.5, ID: 31).

2.10.1.2.2: Lines of evidence for adverse effects and endocrine activity related to T-modality

| Grouping                    | Study ID Matrix | Line(s) of evidence                    | Species | Exposure  | Route of exposure                 | Effect dose | Effect direction | Observed effect  | Assessment of each line of evidence  | Assessment on the integrated line of evidence  | Modality |
|-----------------------------|-----------------|--|---------|-----------|-----------------------------------|-------------|------------------|--|--|--|----------|
| <i>In vitro</i> mechanistic | 3               | Thyroid receptor                       | Rat     | 28 hours  | Uptake from the medium (in vitro) |             | No effect        | No effect  | A positive result was reported in the NIS assay. However, no cytotoxicity measurements were performed in this study. A positive result was obtained for the thyroid receptor assay in Toxcast, although it was reported at cytotoxic concentration only. | There were no T3, T4 and TSH levels measurements in the overall dataset with the exception of the Hershberger assay in male rats, in which no effects were observed in T3 hormone measurement, and an increase in T4 levels were noted. Overall, more data regarding T-mediated activity parameters are deemed necessary in order to reach a conclusion. | T        |
|                             | 4               | Thyroid receptor                       | Rat     | 28 hours  | Uptake from the medium (in vitro) |             | Change           | Dodine acetate is positive for thyroid receptor at cytotoxic concentration. AC <sub>50</sub> (Hill model)= 2.894 |  |  |          |
|                             | 5               | Thyroid receptor                       | Rat     | 28 hours  | Uptake from the medium (in vitro) |             | No effect        | No effect  |  |  |          |

| T-Mediated | 33                     | Thyroid histopathology                  | Rat      | 28 days  | Oral              |             | No effect   | No effect  | Thyroid adenomas and carcinomas were increased in dodine treated rat males in the chronic-carcinogenicity study. Particularly relevant is the increase of thyroid C-cell carcinomas in mid and high dose male groups. Thyroid C-cell adenomas incidence were increased in all dodine treated groups, but without showing a clear dose -relationship. Although these findings were not supported by statistical significance, the incidences exceed the mean and range of the HCD provided for the laboratory. Consequently, these effects were considered relevant for human risk assessment. | Adversity was observed in T-mediated parameters. Thyroid carcinomas and adenomas were increased in dodine-treated groups in male rats, compared with controls, in a dose in which no systemic toxicity was noted. These effects were deemed relevant for human risk assessment. Colloid area, follicular cell height and HDL/LDL ratios were not measured. No adverse effects were related to liver wt. |          |

|          |                 |                      |         |          |                   |                 |                  | right (6%) kidney wt in mid dose F1 female.   |  |   |          |
|          | 50              | Kidney weight        | rat     | 29 week  | Oral              | 400 ppm         | Decrease         | Decrease abs left and right kidney wt (16%) in high dose F2 male pups. Decrease abs left (11%) kidney wt in mid dose F2 male pups in mid dose group.  |  |   |          |
|          | 50              | Kidney weight        | rat     | 29 week  | Oral              | 800 ppm         | Decrease         | Decrease abs left (14%) and right (17%) kidney wt in high dose F2 female pups.  |  |   |          |
|          | 33              | Liver histopathology | rat     | 28 day   | Oral              |                 | No effect        | No effect   | Benign tumours (hepatocellular adenomas) were increased after dodine administration. Liver adenomas appeared at a dose in which systemic toxicity was observed and the results were not supported by statistical significance between groups and controls. Besides, although the occurrence of combined adenomas/carcinomas displayed statistically significance in the top dose female group, it is noteworthy that carcinomas incidence was very similar between dodine-treated groups and their respective controls for both sexes. |   |          |

|          | 47              | Body weight         | dog     | 52 week  | Oral              | 10 mg/kg bw/day | Decrease         | Some dogs from 10 mg/kg bw/day exhibited marked bw loss during first weeks that prompted supplemental feeding.  |                                     |   |          |
|          | 48              | Body weight         | rat     | 2 year   | Oral              | 800 ppm         | Decrease         | Slight statistically significant decreases in bodyweight were recorded in top dose male group throughout week 1-37 (5.2-8.2%) and weeks 85-89 (7-8%), whereas in females were noted throughout whole study (4.1-16.6%)  |                                     |   |          |
|          | 49              | Body weight         | mouse   | 78 week  | Oral              | 750 ppm         | Decrease         | Statistically significantly, lower bodyweights were recorded at top male (3-10%) and female (4-14%) dose groups throughout whole study, compared with controls. At mid dose groups, statistically significant reductions were mainly noted from week 30 to study termination for both sexes (2-5% for males and 4-10% for females, respectively), although sporadic reductions were observed the days before week 30. Overall mean bodyweight gain was statistically significant reduced in mid and high dose male groups (5 and 26%) and in dodine-female treated groups (11, 20 and 35% for low, mid and high dose groups, respectively). |                                     |   |          |

|          | 53              | Necropsy            | rabbit  | 13 day   | Oral              | 100 mg/kg bw/day | Increase         | At high dose group, half of animals showed liquid contents and gaseous distension in caecum, compared with controls   |                                     |   |          |
|          | 54              | Necropsy            | rabbit  | 13 day   | Oral              | 40 mg/kg bw/day  | Increase         | Increased incidence of dark patches in lung lobes in mid (12.5%) and high dose (20%) groups, in which the half of these animals presented breathing difficulties as clinical signs. |                                     |   |          |

### 2.10.1.2.3 Assessment of the integrated lines of evidence and weight of evidence for T-mediated adversity and endocrine activity

#### Weight of evidence for T-mediated adversity

**Table 2.10.1.2.3/1: WoE for T-mediated adversity**

- The thyroid weight was measured in two 28-day oral studies in rats, one of the 90-day studies in rats, the 90-day study in dogs, the 6-week study in dogs and a 2-year study in rats, and in none of them an effect on this parameter was observed depending upon dodine administration. It was also measured in one of the two 1-year oral studies in dogs (ID: 45), where increases in the absolute and relative thyroid weights were shown from 50 ppm of dodine. However, this study was considered only as supportive information, due to the number of deviations that presented from the guideline.
- The thyroid histopathology was examined in one of the 28-day oral studies in rats, the 28-day dermal study in rats, one of the 90-day studies in rats, the 90-day study in mice, the 90-day study in dogs, the 6-week study in dogs, the 52-week study in dogs and 78-week study in mice, and in none of them an effect on this parameter was observed depending upon dodine administration.
- Thyroid histopathology was analysed in a 1-year oral study in dogs (ID: 45), where a shift of follicular epithelium from squamous to cuboidal variety and increased vascularity were observed in a dog at 200 ppm and in two female dogs at 800 ppm. Evidence of stimulation were shown in thyroid glands on males at 800 ppm, with cell type predominantly cuboidal with transition to low columnar and increase in vascularity. However, this study was considered only as supportive information, due to the number of deviations that presented from the guideline.
- Thyroid histopathology was analysed in the 2-year study in rats (ID: 48), where increased incidence of thyroid C-cell adenoma was observed in all male dodine-treated groups, without a dose-response pattern and statistical significance, but out of the HCD (29%, 38%, 33% and 42% for controls, low, mid and high dose groups). Furthermore, increased incidence of thyroid C-cell carcinoma was seen in mid and top dose male group, without dose-response pattern and statistical significance, but exceeding the HCD at these doses (6%, 2%, 12% and 11% for controls, low, mid and high dose group). In addition, increased combined thyroid C-cell adenoma/carcinoma was observed in treated males, without statistical significance, but dose-related and out of the HCD (35%, 40%, 45% and 53% for controls, low, mid and high dose groups).
- In one of the 28-day oral study in rats (ID: 32), an increase in the relative-to-body liver weight was seen in females at 100 mg/kg bw/day. In other of the 28-day oral study in rats (ID: 34), a decrease in absolute and relative-to-body liver weight was shown in females at 800 ppm (equivalent to 76.7 mg/kg bw/day). In the two-generation study in rats (ID: 50), the absolute liver weight was reduced in F1 adults, F1 male pups and F2 pups at 800 ppm. In the 90-day oral study in mice (ID: 39), the relative-to-body liver weight was increased in both sexes at 2500 ppm. In the 78-week study in mice (ID: 49), the relative liver weight was increased in males and females at top dose. In the 52-week study in dogs (ID: 47), the absolute and relative liver weights were increased in females from 10 mg/kg bw/day in females (without histopathological findings associated). Equivocal (decreases and increases) effects were noted in liver weight and, therefore, overall, no adverse effects in liver weight were considered.
- Regarding the parameters sensitive to, but not diagnostic of T, several effects were observed. Changes in adrenal weight were recorded after subacute, subchronic and chronic dodine exposure, at doses with excessive toxicity. In the 28-day oral study in rats (ID: 32), the incidence of adrenals with haemorrhage was increased only at 200 mg/kg bw/day, which was above the maximum tolerated dose. In the two-year study in rats, increased incidence of enlarge and white mottled adrenals were found in females only at the highest dose tested. Increased brain weight were recorded in both sexes in long term and 2-generation toxicity studies, but without histopathological alterations associated. No treatment-related effects were

observed in fertility, foetal development, litter size, pituitary weight and histopathology. Decreased pup weight were recorded in F1 and F2 in the two-generation study (ID: 50), but no relevant decreases were recorded in developmental toxicity studies (ID: 51, 52, 53 and 54). Increased post implantation loss was shown in the developmental toxicity study in rabbits (ID: 54). Tubular hyperplasia in kidney was found in male mice in the chronic toxicity study (ID: 49). In the two-generation study, absolute, but not relative, kidney weight, was reduced in adult and pup rats, which was not deemed biologically relevant. An increased incidence of hepatocellular adenomas were observed in mice in the 78-week study, but it was not supported by statistical significance. Although, the occurrence of combined adenomas/carcinomas displayed statistically significance in the top dose female group, carcinomas incidence was not affected by treatment. Overall, no clear evidences were observed, regarding the parameters 'sensitive to, but not diagnostic of T'.

Therefore, taking into account the effects observed, it is considered that dodine causes T-mediated adversity, mainly based on the incidence of thyroid C-cell adenoma and carcinoma found in the two-year study in rats (ID: 48).

#### Weight of evidence for T-mediated endocrine activity

**Table 2.10.1.2.3/2: WoE for T-mediated endocrine activity**

- The Danish (Q)SAR Database predictions indicate that dodine lacks the potential to interact with the thyroid receptor. Two inconclusive outcomes are obtained from the Leadscape TPO inhibition and NIS models, although the query compound falls outside the applicability domain of the models. These predictions are considered of low relevance.
- There were eight assays on thyroid activity associated with the EDSP21 tab in the CompTox Chemicals Dashboard (Vol.3, AS, B.6.8.3.8). Based on this battery of *in vitro* assays, dodine was inactive in all of them, but active in the thyroid receptor assay TR\_LUC\_GH3\_Antagonist. However, this positive result is reported at a concentration level that is above the limit of cytotoxicity of dodine.
- TSH levels in serum/plasma have not been measured in the available studies. In the Hershberger bioassay (Vol.3, AS, B.6.8.3.5), T3 and T4 levels were measured in peripubertal, orchidopididymectomised male Crl:CD (SD) rats. T3 levels in treated males were similar to the vehicle control rats. T4 levels were statistically significantly increased in male rats at 50 mg of dodine/kg bw/day, without a clear dose-response. T3 and T4 were not measured in any other study.
- In the Sodium-Iodide Symporter (NIS) Assay (Vol.3, AS, B.6.8.3.1), dodine gave a positive response. However, measurements of cytotoxicity were not conducted in the study and the positive response obtained could be adequately assessed.
- In the Thyroid Peroxidase (TPO) Assay (Vol.3, AS, B.6.8.3.2), dodine gave a negative response. However, measurements of cytotoxicity were not conducted and the negative response obtained could not be adequately assessed.

Based on the available data, there is not enough evidence of T-mediated endocrine activity, but data is neither enough to reach a conclusion. The observation of the T4 levels increase in peripubertal males was the only information about the effect of dodine on this hormone. It neither makes the RMS to consider it as an evidence itself of T-mediated activity, nor allows concluding that a potential role of dodine in T-mediated activity should be dismissed.

#### **2.10.1.2.4. Initial analysis of the evidence and identification of relevant scenario for the ED assessment of T-modality**

Since T-mediated adversity has been found and has been sufficiently investigated and endocrine activity has not been sufficiently investigated according to the ED EFSA/ECHA guidance (2018), it corresponds to the scenario 1b (Table 2.10.1.2.4).

**Table 2.10.1.2.4: Selection of relevant scenario for T-modality**

| Adversity based on T-mediated parameters | Positive mechanistic OECD CF level 2/3 Test | Scenario | Next step of the assessment   | Scenario selected |
|--|---|----------|---|-------------------|
| No (sufficiently investigated)           | Yes/No                                      | 1a       | Conclude: ED criteria not met because there is not “T-mediated” adversity   |                   |
| Yes (sufficiently investigated)          | Yes/No                                      | 1b       | <b>Perform MoA analysis</b>   | <b>X</b>          |
| No (not sufficiently investigated)       | Yes   | 2a (i)   | Perform MoA analysis (additional information may be needed for the analysis)  |                   |
| No (not sufficiently investigated)       | No (sufficiently investigated)              | 2a (ii)  | Conclude: ED criteria not met because no T-mediated endocrine activity observed   |                   |
| No (not sufficiently investigated)       | No (not sufficiently investigated)          | 2a (iii) | Generate missing level 2 and 3 information. Alternatively, generate missing “EATS-mediated” parameters. Depending on the outcome move to corresponding scenario |                   |
| Yes (not sufficiently investigated)      | Yes/No                                      | 2b       | Perform MoA analysis  |                   |

#### 2.10.1.2.5. MoA analysis for T-modality

According to the Scenario 1b, adversity has been found based on T-mediated parameters and T-mediated activity has not been sufficiently investigated. A MoA analysis is required to establish the biological plausibility of the link between the observed endocrine activity and potential adverse effects.

#### 2.10.1.2.6. Conclusion on the assessment of T-modality

Considering the available data, T-mediated adversity has been found based on T-mediated parameters and T-mediated activity has not been sufficiently investigated. It corresponds to Scenario 1b. A MoA analysis is required and a conclusion cannot be reached.

#### 2.10.1.3. ED assessment for EAS-modalities

##### 2.10.1.3.1. Analysis of non-experimental data

In accordance with the OECD Conceptual Framework and the ECHA/EFSA GD on ED, Level 1, EAS-related non-test information was gathered for dodine. Qualitative structural activity relationship (QSAR) data was obtained for dodine from the Danish QSAR database, and results are summarised below.

**Table 2.10.1.3.1/1: Results of Danish QSAR database for dodine regarding EAS-modality**

|  | Exp. | Battery | CASE Ultra | Leadscope | SciQSAR |
|--|------|---------|------------|-----------|---------|
| Estrogen Receptor $\alpha$ Binding, Full training set (Human <i>in vitro</i> )     |      | INC_OUT | NEG_OUT    | NEG_OUT   | NEG_OUT |
| Estrogen Receptor $\alpha$ Binding, Balanced Training Set (Human <i>in vitro</i> ) |      | INC_OUT | NEG_OUT    | NEG_OUT   | NEG_OUT |
| Estrogen Receptor $\alpha$ Activation (Human <i>in vitro</i> )                     |      | INC_OUT | NEG_OUT    | NEG_OUT   | INC_OUT |
| Estrogen Receptor Activation, CERAPP data ( <i>in vitro</i> )                      |      | N/A     | N/A        | NEG_IN    | N/A     |
| Androgen Receptor Inhibition (Human <i>in vitro</i> )                              |      | NEG_IN  | NEG_IN     | NEG_IN    | NEG_IN  |

|  |        |     |     |        |     |
|--|--------|-----|-----|--------|-----|
| Androgen Receptor Binding, CoMPARA data ( <i>in vitro</i> )  | NEG_IN | N/A | N/A | NEG_IN | N/A |
| Androgen Receptor Inhibition, CoMPARA data ( <i>in vitro</i> )   | NEG_IN | N/A | N/A | NEG_IN | N/A |
| Androgen Receptor Activation, CoMPARA data ( <i>in vitro</i> )   | NEG    | N/A | N/A | NEG_IN | N/A |
| Key: POS = Positive; NEG = Negative; IN = within the applicability domain of the model; OUT = outside of the applicability domain of the model |        |     |     |        |     |

The outcome predictions obtained from the Danish (Q)SAR Database predictions indicate that dodine lacks the potential to interact with estrogen and androgen receptors. A prediction outcome of inconclusive is obtained for estrogen receptor  $\alpha$ -binding and activation from the Battery algorithm although these predictions are reported to be outside the applicability domain of the models. For this reason, these predictions are considered of low relevance.

### OECD ToolBox

The results of the OECD (Q)SAR Toolbox v.4.2 profilers for dodine in respect to E-related endpoints are displayed below.

**Table 2.10.1.3.1/2. Results of the OECD QSAR Toolbox v.4.2 for dodine**

| Estrogen Receptor Binding, alerts in:  |                                  |
|--|----------------------------------|
| parent only  | Non binder, non cyclic structure |
| metabolites from <i>in vivo</i> Rat metabolism simulator only  | Non binder, non cyclic structure |
| metabolites from Rat liver S9 metabolism simulator only  | Non binder, non cyclic structure |
| rtER Expert System - USEPA, alerts in  |                                  |
| parent only  | No alert found                   |
| metabolites from <i>in vivo</i> Rat metabolism simulator only  | No alert found                   |
| metabolites from Rat liver S9 metabolism simulator only  | No alert found                   |
| OECD QSAR Toolbox v.4.2 profilers  |                                  |
| Profiler predictions are supporting information to be used together with the relevant QSAR predictions |                                  |

### [1] Estrogen receptor binding: Weak binder, OH group

Estrogen receptor (ER) binding is a molecular initiating event similar to protein binding that leads to a series of adverse outcomes, which are typically considered reproductive and development hazards. It is an endpoint where several comprehensive databases exist, which has led to the development of several approaches for using (Q)SARs to predict ER-binding and possible endocrine disruption.

Since the ER-binding is a receptor mediated event, particular organic functional groups, size and shape are critical to binding potency. Chemicals with a single 5- or 6-member carbon ring structure with an unhindered hydroxyl-group (-OH) (a hydroxyl group in the para- or meta-position on the ring and without ortho substituents to the hydroxyl group) (5) are ER binders. Binding potency is related to the size and shape of non-hydroxylated-ring aspect of the molecule, which can be grossly measured by molecular weight.

The incorporated Toolbox ER binding profiling scheme is based on structural and parametric rules extracted from literature sources and supported by experimental data. The ER-binding profiler classifies chemicals as non-binders or binders depending on molecular weight (MW) and structural characteristics of the chemicals:

1. Very strong binders: Chemicals with MW between 200 and 500 Da and two rings with a hydroxyl group connected to each of them.

2. Strong binders: Chemicals with at least one 5-or 6-members carbon ring with an unhindered hydroxyl or amino group and MW between 200 and 500 Da.

3. Moderate binders: Chemicals with at least one 5-or 6-members carbon ring with an unhindered hydroxyl or amino group and MW between 170 and 200 Da.

4. Weak binders: Chemicals with at least one 5-or 6-members carbon ring with an unhindered hydroxyl or amino group and MW less than 170 Da.

If the target chemical does not meet some of the structural and parametric requirements listed above it is classified as Non binder:

- Non binder with impaired hydroxyl or amino group.
- Non binder, MW more than 500 Da.
- Non binders without hydroxyl or amino group.
- Non-binder, non-cyclic.

The OECD Toolbox v.4.2 predicts that dodine lacks the potential to be an ER binder and no alerts were displayed.

## [2] rtER Expert System USEPA: Alkoxyphenols

The rtER Expert System ver.1 – USEPA profiler consists of molecular definitions that mimic the structural criteria of chemical classes that are potential estrogen receptor-binders covered by US EPA Estrogen Receptor Expert System (ERES) The ERES profiler is an effects-based automated system used to predict estrogen receptor binding affinity. In the Toolbox, the rtER Expert System ver.1 – USEPA profiler is used for the purpose of categorization based on the structural definitions of the original ERES chemical classes. The rtER Expert System ver.1 – USEPA profiler is intended for categorization purpose and not for predicting relative binding affinity (RBA). rtER Expert System ver.1

USEPA profiler predicts that dodine meets the criteria of chemical classes that are potential ER binders, on the basis that is an alkoxyphenol substance.

The rtER Expert System ver.1 – USEPA profiler consists of molecular definitions mimic the structural criteria of chemical classes potential estrogen receptor-binders covered by US EPA Estrogen Receptor Expert System (ERES) The ERES profiler is an effects-based automated system used to predict estrogen receptor binding affinity. The Estrogen Receptor Expert System (ERES) Profiler is an effects-based automated system used to predict estrogen receptor binding affinity

### ***ToxCast: CERAPP Potency Level (ER-Related activity) and COMPARA (AR-related activity)***

The ToxCast Model Dashboard includes predictions of the estrogen receptor activity of dodine acetate, based on the Collaborative Estrogen Receptor Activity Prediction Project (CERAPP<sup>Error! Marcador no definido.</sup>). The CERAPP is a large-scale modelling project which has investigated the efficacy of using predictive computational models trained on high-throughput screening data (e.g. from the EDSP21 initiative) to evaluate the ER-related activity of thousands of chemicals, and identify priorities for further testing.

On the other hand, the ToxCast Models Dashboard also includes predictions of the androgen receptor activity of dodine acetate based on the COMPARA. COMPARA is a large scale collaboration between 35 international groups using QSAR models to predict androgen receptor activity using a common training set of 1746 compounds provided by the US EPA. The result is consensus model of AR agonist activity that is run against the DSSTox chemical library that aims to identify priorities for further testing.

The CERAPP and COMPARA predictions for estrogen and androgen activity are summarised in the following table:

**Table 2.10.1.3.1/3. Results of the CERAPP and COMPARA predictions for dodine acetate.**

| Model                                  | Receptor | Agonist  | Antagonist | Binding  |
|--|----------|----------|------------|----------|
| CERAPP Potency Level (Consensus)       | Estrogen | 0        | 0          | 0        |
| CERAPP Potency Level (From Literature) | Estrogen | Inactive | Inactive   | Inactive |
| COMPARA (Consensus)                    | Androgen | 0        | 0          | 0        |

As noted, dodine acetate displayed inactive results for estrogen and androgen receptor activities.

**2.10.1.3.2. US EPA CompTox Chemicals Dashboard**

***Estrogen receptor bioassays***

Dodine acetate was tested in 6 assays included in the ToxCast ER Bioactivity Model component. (Study ID Matrix No: 9-14). Dodine acetate gave negative results in 5 of these assays. A positive result was obtained in the ERa\_LUC\_VM7\_Agonist assay. The AC<sub>50</sub> value was 3.34 x10<sup>-5</sup> μM (Hill Model). The limit of cytotoxicity for this assay was reported to be 0.183 μM. The assay presented a flag of ‘less than 50% efficacy and AC<sub>50</sub> less than lowest concentration tested’.

**Table 2.10.1.3.2/1: Summary of US EPA ToxCast EDSP21- estrogenic bioactivity assays for dodine acetate.**

| Assay endpoint                                  | Study ID Matrix | Assay type               | Organism | Result   | AC <sub>50</sub> <sup>#</sup> | Flag   |
|---|-----------------|--------------------------|----------|----------|-------------------------------|--|
| TOX21_ERa_BLA_Agonist_ratio                     | 9               | beta lactamase induction | human    | Inactive | -                             | -  |
| TOX21_ERa_BLA_Antagonist_ratio                  | 10              | beta lactamase induction | human    | Inactive | -                             | -  |
| TOX21_ERa_BLA_Antagonist_viability              | 11              | ATP content              | human    | Inactive |                               |  |
| TOX21_ERa_LUC_VM7_Agonist                       | 12              | luciferase induction     | human    | Active   | 3.34 x 10 <sup>-5</sup>       | Less than 50% efficacy. AC50 less than lowest concentration tested |
| TOX21_ERa_LUC_VM7_Antagonist_specificity        | 13              | luciferase induction     | human    | Active   | -                             | -  |
| TOX21_ERa_LUC_VM7_Antagonist_0.5nM_E2_viability | 14              | ATP content              | human    | Inactive | -                             | -  |

<sup>#</sup> Chemical concentration (in μM) at which 50% of the maximum response is achieved.

***Androgen receptor bioassays***

Dodine acetate was tested in 8 assays included in the ToxCast AR Bioactivity Model (Study ID Matrix No: 15-22). Dodine acetate is reported to be inactive in 6 assays and is reported active in 2 assays: AR\_BLA\_Antagonist\_viability and AR\_LUC\_MDAKB2\_Antagonist\_0.5nM\_R1881\_viability.

**Table 2.10.1.3.2/2: Summary of US EPA ToxCast EDSP21- androgenic bioactivity assays for dodine acetate.**

| Assay endpoint                                       | Study ID Matrix | Assay type               | Organism | Result   | AC <sub>50</sub> <sup>#</sup> | Flag  |
|--|-----------------|--------------------------|----------|----------|-------------------------------|---|
| TOX21_AR_BLA_Agonist_ratio                           | 15              | beta lactamase induction | human    | Inactive | -                             | -   |
| TOX21_AR_BLA_Antagonist_ratio                        | 16              | beta lactamase induction | human    | Inactive | -                             | -   |
| TOX21_AR_BLA_Antagonist_viability                    | 17              | ATP content              | human    | Active   | 2.202                         | Only highest concentration above baseline, active less than 50% efficacy, borderline active |
| TOX21_AR_LUC_MDAKB2_Agonist                          | 18              | luciferase induction     | human    | Inactive | -                             | -   |

| TOX21_AR_LUC_MDAKB2_Antagonist_0.5nM_R1881_viability | 20              | ATP content              | human    | Inactive | -                             | -   |

| Assay endpoint                                      | Study ID Matrix | Assay type           | Organism | Result   | AC <sub>50</sub> <sup>#</sup> | Flag |
|---|-----------------|----------------------|----------|----------|-------------------------------|------|
| TOX21_AR_LUC_MDAKB2_Antagonist_10nM_R1881           | 21              | luciferase induction | human    | Inactive | -                             | -    |
| TOX21_AR_LUC_MDAKB2_Antagonist_10nM_R1881_viability | 22              | ATP content          | human    | Inactive | -                             | -    |

<sup>#</sup> Chemical concentration (in  $\mu\text{M}$ ) at which 50% of the maximum response is achieved

The reported AC<sub>50</sub> value for the AR\_BLA\_Antagonist\_viability assay was determined to be 2.20  $\mu\text{M}$  (Hill Model), and flags of ‘only highest concentration above baseline, less than 50% efficacy, borderline active’ were displayed. On the other hand, the reported AC<sub>50</sub> value for the AR\_LUC\_MDAKB2\_Antagonist\_0.5nM\_R1881\_viability assay was determined to be 1.612  $\mu\text{M}$  (Hill Model), and a flag of ‘noisy data’ was displayed.

Both results were above the limit of cytotoxicity for the assays (0.183  $\mu\text{M}$ ), so the reliability is low.

### Steroidogenesis bioassays

Dodine acetate was tested in 2 assays included in the ToxCast Steroidogenesis Bioactivity Model (Study ID Matrix No.: 23-24), and negative results were obtained for both assays.

**Table 2.10.1.3.2/3: Summary of US EPA ToxCast EDSP21- Steroidogenesis bioactivity assays for dodine acetate.**

| Assay endpoint                       | Study ID Matrix | Assay type           | Organism | Result   | AC <sub>50</sub> <sup>#</sup> | Flag |
|--------------------------------------|-----------------|----------------------|----------|----------|-------------------------------|------|
| TOX21_Aromatase_Inhibition           | 23              | Luciferase induction | human    | Inactive | -                             | -    |
| TOX21_Aromatase_inhibition_viability | 24              | ATP content          | human    | Inactive | -                             | -    |

### 2.10.1.3.3. Have EAS-mediated parameters been sufficiently investigated?

The available dataset of *in vivo* mammalian toxicology studies for dodine consists of short-term studies (7 and 28 days) conducted in rodents, sub-chronic studies (42, 56, 90 and 100 days) conducted in rodents and dog, carcinogenicity studies conducted in rodents, one 2-generation toxicity study conducted in rats, and prenatal developmental toxicology studies conducted in rats and rabbits. It was noted that much of the available data pre-dates revisions that were made to the OECD Test Guidelines to include EAS-mediated parameters.

Table 14 of the ECHA/EFSA GD on ED provides a list of relevant EAS-mediated parameters that may be investigated in the OECD CF Level 4 and 5 *in vivo* OECD TG compliant mammalian toxicology studies. Using the currently available set of toxicological data for dodine, the table 2.10.1.3.3/1 summarises the available information on EAS-mediated parameters.

To have the EAS-mediated adversity with regard to humans and mammals sufficiently investigated, all the data requirements of the specific Regulations, must be fulfilled. This should include all the ‘EAS-mediated’ parameters foreseen to be investigated in an extended one-generation reproductive toxicity study (EOGRTS; OECD TG 443; with cohort 1a/1b including the mating of cohort 1b to produce the F2 generation (OECD, 2012, updated on 2018)) or a two-generation reproductive toxicity study (OECD TG 416; test protocol according to latest version of January 2001 (OECD, 2001)).

**Table 2.10.1.3.3/1: Summary of EAS-mediated parameters investigated in mammalian toxicology studies**

| EAS-mediated parameters | OECD Test guideline | Sufficiently investigated?   |
|-------------------------|---------------------|--|
|                         |                     | <p><b>Overall conclusion: No (not sufficiently investigated)</b><br/>Based on the lack of OECD 416 (2001 version) and 443 studies.</p> <p>The following studies are available instead (see parameters covered in table below):</p> <ul style="list-style-type: none"> <li>-Two generation study in rats (FIFRA 83-4; OECD 416) and repeated dose studies.</li> </ul> |
| <b>Estradiol level</b>  | 408 (optional)      | No data  |

| <b>Follicle stimulating hormone (FSH) level</b> | 408 (optional)                                     | No data  |
| <b>Luteinising hormone (LH) level</b>           | 408 (optional)                                     | No data  |
| <b>Testosterone level</b>                       | 408 (optional)                                     | No data  |
| <b>Accessory sex organs histopathology</b>      | 408, 421, 451-3                                    | No data  |
| <b>Age at first oestrus</b>                     | OPPTS 890.1450                                     | No data  |
| <b>Age at balanopreputial separation</b>        | 426, 416, 443                                      | No data  |
| <b>Age at vaginal opening</b>                   | 426, 416, 443                                      | No data  |
| <b>Anogenital distance (AGD)</b>                | 414, 421, 426, 416, 443                            | No data  |
| <b>Cervix histopathology</b>                    | 407, 408, 415, 422, 451-3, 416, 443                | Cervix histopathology were performed in the long term/chronic toxicity studies in rodents and in the 2-generation toxicity study in rats.  |
| <b>Coagulating gland histopathology</b>         | 407, 408, 415, 422, 451-3, 416, 443                | Coagulating gland histopathology was only carried out in the 2-generation toxicity study in rats.  |
| <b>Coagulating gland weight</b>                 | 407, 421, 422, 416, 443                            | Coagulating gland weight was measured together with seminal vesicles in the 2-generation toxicity study in rats.   |
| <b>Cowper's gland weight</b>                    | 421 (optimal), 422 (optional)                      | No data. (Only in the Hershberger OECD TG 441 assay).  |
| <b>Epididymis histopathology</b>                | 407, 408, 415 (optional) 421, 422, 451-3, 416, 443 | Epididymis histopathology was performed in the 28 and 90 day studies in rodents, in 90 day and 1 year studies in dog, in long term/chronic toxicity studies in rodents and in the 2-generation toxicity study in rats. |

|   |   |   |
|---|---|---|
| <b>Epididymis weight</b>  | 407, 408, 421, 422, 451-3, 416, 443                       | Epididymis weight was measured in the 28-day study in rats, in 90-day study in dog, in the long term/chronic toxicity studies in rats and in the 2-generation toxicity study in rats.                                 |
| <b>Oestrus cyclicity</b>  | 407 (optional), 408, 421, 422, 416, 443                   | Oestrus cyclicity was conducted in the 2-generation toxicity study conducted in rat.  |
| <b>Glans penis weight</b>   | 421 (optimal), 422 (optional)                             | No data. (Only in the Hershberger OECD TG 441 assay).   |
| <b>Genital abnormalities</b>  | 414, 415, 421, 422, 416, 443                              | Genital abnormalities were mainly checked in the 2-generation toxicity study conducted in rats.   |
| <b>LABC weight</b>  | 421 (optimal), 422 (optional), OPPTS 890.1500             | No data. (Only in the Hershberger OECD TG 441 assay).   |
| <b>Mammary gland histopathology (male)</b>                                    | 407 (optional), 408, 422, 443, 451-3 (optional)           | Mammary gland histopathology (male) was performed in one 28-day toxicity studies in rats, in 90-day study in dogs and in the carcinogenicity studies in rodents.  |
| <b>Mammary gland histopathology (female)</b>                                  | 407, 408, 451-3, 443                                      | Mammary gland histopathology (female) was performed in one 28-day toxicity studies in rats, in one 90-day study in mice, in 90-day and 1-year toxicity studies in dogs and in the carcinogenicity studies in rodents. |
| <b>Nipple development</b>   | 421, 422, 443   | No data   |
| <b>Ovary histopathology</b>   | 407, 408, 415 (optional) 421, 422, 426, 451-3, 416, 443   | Ovary histopathology was performed in one 28, 56 and 90-day toxicity studies in rodents, in 90-day and 1-year study in dogs, in carcinogenicity studies in rodents, and in the 2-generation toxicity study in rats.   |
| <b>Ovary weight</b>   | 407 (optional), 408, 421 (optional), 422, 451-3, 416, 443 | Ovary weight was measured in one 28 and 90-day toxicity studies in rodents, in 42-day and 1-year study in dogs, in carcinogenicity studies in rodents, and in the 2-generation toxicity study in rats.                |
| <b>Oviduct histopathology</b>   | 408, 415 (optional), 443                                  | Oviduct histopathology was performed in the 2-generation toxicity study in rats and in the 28-day dermal study in rats.   |
| <b>Prostate histopathology (with seminal vesicles and coagulating glands)</b> | 407, 408, 415 (optional) 421, 422, 426, 451-3, 416, 443   | Prostate histopathology was performed in two 90-day toxicity studies in rodents, in 90-day and 1-year study in dogs, in carcinogenicity studies in rodents, and in the 2-generation toxicity study in rats.           |

|  |  |   |
|--|--|---|
| <b>Prostate weight</b>                     | 407, 408, 421, 422, 416, 443   | Prostate weight was measured in the 90-day study in dogs, in the carcinogenicity study in rats, and in the 2-generation toxicity study in rats.   |
| <b>Seminal vesicles histopathology</b>     | 407, 408, 415 (optional), 422, 451-3, 416, 443   | Seminal vesicles histopathology was performed in the 28 and 90-day toxicity studies in rodents, in the carcinogenicity studies in rodents, and in the 2-generation toxicity study in rats.  |
| <b>Seminal vesicles weight</b>             | 407, 408, 421, 422, 416, 443   | Seminal vesicles weight was performed in the 2-generation toxicity study in rats.   |
| <b>Sperm morphology</b>                    | 408 (optional), 416, 443   | Sperm morphology was performed in the 2-generation toxicity study in rats.  |
| <b>Sperm motility</b>                      | 408 (optional), 416, 443   | Sperm motility was performed in the 2-generation toxicity study in rats.  |
| <b>Sperm numbers</b>                       | 408 (optional), 416, 443   | Sperm number was performed in the 2-generation toxicity study in rats.  |
| <b>Testis histopathology</b>               | 407, 408, , 415 (optional) 421, 422, 451-3, 416, 443   | Testis histopathology was performed in 28-day toxicity studies in rats, in 90-day studies in rat and mice, in 42 and 90-day and 1-year study in dogs, in carcinogenicity studies in rodents, and in the 2-generation toxicity study in rats.            |
| <b>Testis weight</b>                       | 407, 408, 421, 422, 451-3, 416, 443  | Testis weight was measured in 28-day toxicity studies in rats, in 90-day studies in rat and mice, in 42 and 90-day and 1-year study in dogs, in carcinogenicity studies in rodents, and in the 2-generation toxicity study in rats.                     |
| <b>Uterus histopathology (with cervix)</b> | 407, 408, 415 (optional), 421 (optional), 422, 451-3, 416, 443                                 | Uterus histopathology was performed in one 28-day toxicity study in rats, in 90-day studies in rat and mice, in 90-day and 1-year studies in dogs, in carcinogenicity studies in rodents, and in the 2-generation toxicity study in rats.               |
| <b>Uterus weight (with cervix)</b>         | 407 (optional), 408, 414 (gravid uterus), 415 (optional), 421 (optional), 422, 451-3, 416, 443 | Uterus weight was measured in one 28-day toxicity study in rats, in one 90-day study in dogs, in the carcinogenicity study in rats, in the 2-generation toxicity study in rats, and in the developmental toxicity studies conducted in rat and rabbits. |
| <b>Vagina histopathology</b>               | 407, 408, 415 (optional), 422, 451-3, 416, 443   | Vaginal histopathology was performed in 90-day and 1-year studies in dogs, in the carcinogenicity study in rats and mice, and in the 2-generation toxicity study in rats.   |
| <b>Vaginal smear</b>                       | 407 (optional), 408, 421, 422, 416, 443  | No data   |

**Table 2.10.1.3.3/2: EAS-mediated parameters not measured**

| - Anogenital distance measurement   | - Genital abnormalities |

Regarding to the EAS-mediated endocrine activity:

E-modality: It is considered sufficiently investigated based on the estrogenic activity output data from the US EPA ToxCast Bioactivity Model.

A-modality: It is considered sufficiently investigated based on the output data from “Hershberger bioassay in rats’ (ID::31; OECD TG 441).

S-modality: It is considered sufficiently investigated based on the output data from “H295R Steroidogenesis assay” (ID: 30; OECD TG 456), and the “*In vitro* aromatase inhibition using human recombinant microsomes assay” (ID: 29) in line with OPPTS 890.1200.

Therefore, it is considered that EAS-mediated endocrine activity have been sufficiently investigated.

2.10.1.3.4. Lines of evidence for adverse effects and endocrine activity related to EAS-modality

| Grouping                    | Study ID Matrix | Effect target             | Species | Exposure | Route of administration           | Effect dose    | Effect direction | Observed effect  | Assessment of each line of evidence  | Assessment on the integrated line of evidence  | Modality |
|-----------------------------|-----------------|---------------------------|---------|----------|-----------------------------------|----------------|------------------|--|--|--|----------|
| <i>In vitro</i> mechanistic | 9               | Estrogen receptor         | Human   | 24 hour  | Uptake from the medium (in vitro) |                | No effect        | No effect  | Dodine showed one positive result in one mRNA ESR1 induction assay, however the outcome is of low reliability due to the flags presented by the assay. On the other hand, dodine displayed negative results for ER agonist or antagonist activity in stably transfected hER-HeLa-9903 cell line. | The weight of evidence of the <i>in vitro</i> EAS-modalities assays showed that dodine, could be a potential AR-antagonist, without ruling out a possible interaction with components of the steroidogenesis pathway, such as aromatase CYP19. | E        |
|                             | 10              | Estrogen receptor         | Human   | 24 hour  | Uptake from the medium (in vitro) |                | No effect        | No effect  |  |  |          |
|                             | 11              | Estrogen receptor         | Human   | 24 hour  | Uptake from the medium (in vitro) |                | No effect        | No effect  |  |  |          |
|                             | 12              | Estrogen receptor         | Human   | 22 hour  | Uptake from the medium (in vitro) | 3.34 x 10-5 µM | Change           | Dodine acetate is active for estrogen (ESR1) mRNA induction assays. AC50 (hill model) = 3.34 x 10-5 µM. The assay presents two flags: Less than 50% efficacy and AC50 less than lowest concentration tested. |  |  |          |
|                             | 13              | Estrogen receptor         | Human   | 22 hour  | Uptake from the medium (in vitro) |                | No effect        | No effect  |  |  |          |
|                             | 14              | Estrogen receptor         | Human   | 22 hour  | Uptake from the medium (in vitro) |                | No effect        | No effect  |  |  |          |
|                             | 27              | Estrogen receptor agonist | Human   | 3 hour   | Uptake from the medium (in vitro) |                | No effect        | Dodine technical was classified as negative in the ER agonist assay, since the RPCMax did not exceed 10% of the response of the positive control in two  |  |  |          |

| Grouping | Study ID Matrix | Effect target                | Species | Exposure | Route of administration           | Effect dose   | Effect direction | Observed effect   | Assessment of each line of evidence  | Assessment on the integrated line of evidence | Modality |
|----------|-----------------|------------------------------|---------|----------|-----------------------------------|---------------|------------------|---|--|---|----------|
|          |                 |                              |         |          |                                   |               |                  | independent experiments.  |  |   |          |
|          | 27              | Estrogen receptor Antagonist | Human   | 3 hour   | Uptake from the medium (in vitro) |               | No effect        | No IC30 values could be derived from any of the replicates for the ER antagonist assay.   |  |   |          |
|          | 15              | Androgen receptor            | Human   | 24 hour  | Uptake from the medium (in vitro) |               | No effect        | No effect   | Dodine showed two positive results in agonist and antagonist <i>in vitro</i> Toxcast assays. However, the AC50 values derived were higher than the concentration limit for cytotoxicity. On the other hand, antagonist activity was noted in stably transfected AR-EcoScreen cell line in presence of 5 $\alpha$ -dihydrotestosterone (DHT). IC30 = 0.05 and 1 $\mu$ M for each of the two available replicates. | A   |          |
|          | 16              | Androgen receptor            | Human   | 24 hour  | Uptake from the medium (in vitro) |               | No effect        | No effect   |  |   |          |
|          | 17              | Androgen receptor            | Human   | 24 hour  | Uptake from the medium (in vitro) | 2.2 $\mu$ M   | Change           | Dodine acetate is active in HEK293T cell viability assay. AC50 (hill model)= 2.2. The assays presents the flag: Only highest concentration above baseline, active. Less than 50% efficacy. Borderline active. The limit of cytotoxicity was reported to be 0.183 $\mu$ M. |  |   |          |
|          | 18              | Androgen receptor            | Human   | 24 hour  | Uptake from the medium (in vitro) |               | No effect        | No effect   |  |   |          |
|          | 19              | Androgen receptor            | Human   | 24 hour  | Uptake from the medium (in vitro) | 1.612 $\mu$ M | Change           | Dodine acetate is active for androgen receptor (AR) antagonist transcriptional gene expression assay in MDA-kb2 cell line. AC50 (hill   |  |   |          |

| Grouping | Study ID Matrix | Effect target                | Species | Exposure   | Route of administration           | Effect dose  | Effect direction | Observed effect   | Assessment of each line of evidence   | Assessment on the integrated line of evidence | Modality |
|----------|-----------------|------------------------------|---------|------------|-----------------------------------|--------------|------------------|---|---|---|----------|
|          |                 |                              |         |            |                                   |              |                  | model) = 1.612 $\mu$ M. The assay presents the flag: noisy data. The limit of cytotoxicity was reported to be 0.183 $\mu$ M.  |   |   |          |
|          | 20              | Androgen receptor            | Human   | 24 hour    | Uptake from the medium (in vitro) |              | No effect        | No effect   |   |   |          |
|          | 21              | Androgen receptor            | Human   | 24 hour    | Uptake from the medium (in vitro) |              | No effect        | No effect   |   |   |          |
|          | 22              | Androgen receptor            | Human   | 24 hour    | Uptake from the medium (in vitro) |              | No effect        | No effect   |   |   |          |
|          | 28              | Androgen receptor Agonist    | Human   | 24 hour    | Uptake from the medium (in vitro) |              | No effect        | No effect   |   |   |          |
|          | 28              | Androgen receptor Antagonist | Human   | 24 hour    | Uptake from the medium (in vitro) |              | Change           | Dodine technical was classified as positive in the AR antagonist assay, since an IC30 value could be calculated in two independent runs (0.05 and 1 $\mu$ M, respectively). |   |   |          |
|          | 23              | CYP19                        | Human   | 24 hour    | Uptake from the medium (in vitro) |              | No effect        | No effect   | Dodine showed ability to inhibit aromatase activity in an <i>in vitro</i> assays using microsomal proteins. IC50= 56.8 $\mu$ M. On the other hand, dodine technical was negative for testosterone or estradiol induction. |   | S        |
|          | 24              | Cellular proliferation       | Human   | 24 hour    | Uptake from the medium (in vitro) |              | No effect        | No effect   |   |   |          |
|          | 29              | Androstenedione (in vitro)   | Human   | 15 Minutes | Uptake from the medium (in vitro) | 56.8 $\mu$ M | Decrease         | The outcome of the study indicates that dodine inhibits the activity of aromatase with decreases in aromatase   |   |   |          |

| Target organ toxicity | 33              | Kidney histopathology                                | rat     | 28 day   | Oral                    | 1000 ppm    | Increase         | In female kidneys, mineralization of the cortico-medullary junction (5/10 vs 2/10 in control) increased at 1000 ppm. In both sexes, very slight increase in fibrosis (1/10 vs 0/10 in control, per sex) at 1000 ppm. Lower doses not tested. | Tubular hyperplasia was found in top dose male mice in chronic toxicity study. On the other hand, low incidences and equivocal histological effects (increase/decrease) were noted in other toxicity studies. Additionally, in 2-generation reproductive toxicity study, abs kidney wt, but no rel were reduced in adult and pup rats. These findings were not deemed adverse nor biologically relevant. | Hepatocellular adenomas were increased in top dose male/female dose groups in the 78 week mice-chronic toxicity study. This effect did not show a clear dose response nor statistical significance. Signs of systemic toxicity was noted at this dose. No other adverse histopathology findings in the liver were noted in another species in the toxicology studies within the dossier. Overall, these effects were not considered |          |

|          | 33              | Liver histopathology | rat     | 28 day   | Oral                    |                 | No effect        |   | Benign tumours (hepatocellular adenomas) were increased after dodine administration. Liver adenomas appeared at a dose in which systemic toxicity was observed and the results were not supported by statistical significance between groups and controls. Besides, although the occurrence of combined adenomas/carcinomas displayed statistically significance in the top dose female group, it is noteworthy that carcinomas incidence was very similar between dodine-treated groups and their respective controls for both sexes. |   |          |

### 2.10.1.3.5. Assessment of the integrated lines of evidence and weight of evidence for EAS-mediated adversity and endocrine activity.

#### WoE for EAS-mediated adversity

This section provides the lines of evidence for the *in vivo* mammalian toxicology studies (Level 4 and 5) using test substance dodine in respect of the EAS-modality. The following sections provide an analysis of the integrated lines of evidence and report the weight of evidence in respect of EAS-mediated adversity.

#### Regarding EAS-mediated parameters

-Most of the EAS-mediated parameters were measured in the long-term/carcinogenicity toxicity studies conducted in rat (ID: 48) and mice (ID: 49), and in the 2-generation toxicity conducted in rats (ID: 50). Furthermore, several short-term/repeated toxicity studies were conducted in rat, mice and dog.

No clear toxicologically significant changes or pattern of effects were reported in the repeated exposure studies in EAS mediated male target organs:

-Increased relative testis weight was increased in high dose F1 males in 2-generation toxicity study conducted in rats (ID: 50). No histopathological changes were associated to this finding. In addition, no differences were noted regarding reproductive parameters that draw attention to a problem in male fertility. No alterations regarding testis weight or histopathology abnormalities were recorded in other toxicity studies contained in the dossier.

- Epididymis relative weight was increased (mid and high doses) in two year rat study (ID: 48), and in F1 adult males (high dose) from 2-generation toxicity study (ID: 50).

-An increased, not dose related of prostate atrophy incidences were noted in male treated groups (1.5%, 3.3%, 8.2% y 4.3% for controls, low, mid and high dose groups, respectively) in 2-year carcinogenicity study conducted in rats.

- Seminal vesicle atrophy (3/10) at 200 mg/kg bw/day (above MTD, pre-terminal) was noted in 28-day study in rats (ID: 32). Controls and lower doses were not tested.

- Regarding sperm evaluation, the available study (ID 50) deviated from current guidelines because sperm morphology was evaluated in 100 sperm/male instead of 200. However, in the 100 sperm examined/male in the study, there were no significant differences in the percent motility, mean sperm concentration, and sperm morphology in P and F1 dodine-treated males compared with controls.

On the other hand, no clear toxicologically significant changes or pattern of effects were reported in the repeated exposure studies in EAS mediated female target organs:

-An increase, not statistically significant and not dose related, in the relative uterus weight was observed in top dose female group in the carcinogenicity study in rats (ID: 48). A slight increase, not dose related, in the mean uterus weight was found in mid and high dose groups (5% and 7% for mid and high dose groups, respectively) in the main developmental toxicity study in rats (ID: 52).

- In the 2-year carcinogenicity study in rats (ID: 48), benign ovary cystadenomas, not dose related, were noted in 0/37 (0%), 3/32 (9%), 5/36 (14%) and 2/36 (6%) of females from the 0, 200, 400 and 800 ppm dose groups, respectively. These findings were ruled out due to no dose related increase were noted, and no another histopathological findings in ovary were revealed in other toxicity studies within the dossier. On the other hand, increase relative left ovary/oviduct wt was described in F1 females (11%) at high dose from 2-generation toxicity study (ID: 50).

- No treatment-related differences were revealed between dodine treated groups and controls regarding oestrus cyclicity in the 2-generation toxicity study (ID: 50).

-Regarding mammary gland histopathology, higher incidence of thickened mammary glands was observed in 1-year treated dogs females (ID: 47), although this effect was not dose-response. On the other hand, in the 2-year carcinogenicity study in rats (ID: 48), an increase, not dose related, of malignant adenocarcinomas incidences were noted in female mid dose group (10, 14.5, 24.6 and 12.9% for control, low, mid and high dose groups).

#### Regarding sensitive to, but not diagnostic of EATS parameters:

- Increases adrenal wt were recorded in the 28-day study in rats (ID: 32) and in the 2-generation toxicity study (ID: 50). A reduction without dose response was observed in the 2-year carcinogenicity study in rats (ID: 48).

-Increased incidences of relative brain weight were recorded in both sexes in long term (ID: 48-49) and in 2-generation toxicity studies (ID: 50). No histopathological alternations were further described. Potential neurotoxic clinical signs were mainly recorded in chronic and developmental toxicity studies.

-In the two-generation toxicity study conducted in rats (ID: 50):

.No effects were noted on fertility in males or females.

.No effects were observed in reproductive/pregnancy parameters in females.

.No genital abnormalities were noted.

.Decreased pup weight were recorded in both generations in rat generational study at doses in which maternal toxicity was described. No relevant decreases were further recorded in developmental toxicity studies.

-In the main developmental toxicity studies conducted in rats (ID: 52) and rabbits (ID 54):

.No effects were observed in reproductive/pregnancy parameters in the main developmental toxicity study in rats (ID 52).

.Increased of post implantation losses and late resorption were recorded in the developmental toxicity study in rabbits (ID: 54) at mid (40 mg/kg bw/day) and high doses (80 mg/kg bw/day), without showing statistical significance and a clear dose-relationship. These findings were seen in presence of maternal toxicity at 80 mg/kg bw/day and without clear maternal toxicity at 40 mg/kg bw/day.

.No effects on foetal development, no external, skeletal or visceral abnormalities have been reported in the developmental studies (rats and rabbits).

#### Target organ toxicity

-In the chronic/carcinogenicity study in mice (ID: 49), increased incidences of hepatocellular adenomas were observed at high dose groups for both sexes (13%, 12%, 15% and 23% for controls, low, mid and high dose males groups; and 0%, 2%, 2% and 7% for controls, low, mid and high dose females groups, respectively), in which a statistically significant trend was displayed for females. On the other hand, no relevant increases were noted regarding hepatocellular carcinomas in dodine-treated groups (male or females). When the effects were combined, increased incidences were also observed in high dose groups (17%, 12%, 20% and 25% for controls, low, mid and high dose males groups; and 0%, 3%, 2% and 8% for controls, low, mid and high dose females groups, respectively), showing a significant trend test in females, and the only significant group comparison difference with controls was for combined adenomas and carcinomas in females given 1500 ppm dose. Signs of systemic toxicity were described at mid and high dose dose. Additionally, no other adverse histopathology findings in the liver were noted in another species in the toxicology studies within the dossier. Overall, these effects were not considered relevant for human risk assessment.

-No other relevant findings were observed regarding target organ toxicity in the subacute, subchronic or chronic toxicity studies provided in the dossier.

#### **WoE for EAS-mediated activity**

The available dataset of *in vitro* mechanistic assays showed positive/active results for ER and AR bioactivity models. Toxcast ER bioactivity model showed one active/positive assay (ID: 12). The reported AC<sub>50</sub> value for this assay is less than the lowest concentration tested in the experiment. The data and curve fitting for this study also appear to be scattered and do not show a clear response, so the relevance of this result is low. Furthermore, dodine technical is also reported inactive in the CERAPP models.

On the other hand, Toxcast AR bioactivity model displayed two active/positive result (ID: 17 and 19). Both positive results are reported at a concentration level that is above the limit of cytotoxicity of dodine and presented flags that compromise the reliability of the assays. Additionally, predictions from COMPARA model indicate that dodine is inactive for AR agonist, antagonist, and AR binding.

To end, negative results were displayed in the only two available Toxcast Steroidogenesis bioactivity models.

E-modality: An *in vitro* estrogen receptor transactivation (ER-STTA) assay, according to OECD TG 455 was conducted (ID 27). Dodine displayed negative results for agonist and for antagonist effects on the estrogen receptor.

A-modality: An *in vitro* androgen receptor transactivation (AR-STTA) assay, according to OECD 458 was conducted (ID 28). The outcome of the AR agonist assay showed that the RPC<sub>max</sub> value was below 10% of the positive control in two replicates. On the other hand, the outcome of the AR antagonist assay showed that dodine was able to reduce AR-transactivation of luciferase gene expression in presence of dihydrotestosterone (DHT). In this assay, IC<sub>50</sub> values could not be derived, but IC<sub>30</sub> values could be derived from replicate 1 (0.05µM) and replicate

3 (1  $\mu\text{M}$ ). Based on these results, dodine technical may be deemed positive in the AR antagonist assay and negative for AR agonist assay.

A Hershberger assay (ID 31) was conducted in order to follow up the positive results *in vitro* in the AR-STTA antagonist assay. Both agonist and antagonist groups (three doses of 5, 15, 50 mg/kg bw each) and corresponding controls were included in the study. No changes were observed in the five androgen-dependent organs (Cowper's gland, seminal vesicles, LABC muscle, glans penis and ventral prostate) upon exposure to dodine, both in the agonist and antagonist part of the assay.

Considering the mixed positive/negative results observed *in vitro* for the androgen modality, and the clearly negative results observed in the *in vivo* Hershberger assay, the effects of dodine seen *in vitro* are not relevant in the *in vivo* model. Therefore, overall the database shows no endocrine activity with regard to the androgen modality.

**S-modality:** An aromatase assay according to OPPTS 890.1200 was conducted (ID: 29). This is a cell-free assay that directly measures the activity of the aromatase enzyme. Dodine caused inhibition of the aromatase enzyme with an  $\text{IC}_{50}$  of 56.8  $\mu\text{M}$ . Furthermore, a steroidogenesis assay according to OECD 456 was conducted (ID 30). Dodine did not induce or inhibit the production of testosterone and  $17\beta$ -estradiol in two independent experiments up to the cytotoxicity limit (0.5  $\mu\text{M}$ ). Consequently, unlike previous aromatase activity test cell-free assay, neither aromatase (CYP19) enzymatic activity, nor the activity of other enzymes from steroidogenesis pathway was affected in the H295R steroidogenesis assays.

On the other hand, the Hershberger assay (ID 31) conducted with dodine also provides relevant information on possible effects on the steroid pathways. This study serves as a mechanistic *in vivo* screening assay for androgen agonists or antagonists and  $5\alpha$ -reductase inhibitors. So, the lack of effects in androgen dependent tissues (agonist or antagonist) shows that no effects occurred in the levels of steroid hormones upon exposure to dodine.

Overall, although the enzyme-based assay showed inhibition of the aromatase enzyme, no effect on steroidogenesis/aromatase enzyme gene transactivation was seen in cell-based assays. In addition, in the *in vivo* mechanistic study (Hershberger assay), no effects were observed that could be related to changes in the steroid hormones pathways. Therefore, the dataset did not shows endocrine activity with regard to the steroidogenesis modality.

#### 2.10.1.3.6. Selection of relevant scenario for the ED assessment of EAS-modality

No OECD TG 443 or OECD TG 416 (according to latest version of January 2001) studies have been conducted with dodine. However, based on a weight of evidence approach, no EAS-mediated adversity have been identified in the available dataset. On the other hand, the positive anti-androgenic activity displayed *in vitro* was not further confirmed in the *in vivo* Hershberger assay. Moreover, the positive *in vitro* inhibition of aromatase activity in a cell-free system was not further confirmed in the *in vitro* cell based steroidogenesis assay nor in the *in vivo* Hershberger assay. Overall, it can be concluded that no EAS-mediated adversity nor activity were found, therefore it corresponds to the scenario 2a (ii).

**The relevant scenario for the EAS-modality is identified as 2a (ii).**

**Table 2.10.1.3.6: Identification of relevant scenario for EAS-modality**

| Adversity based on EAS-mediated parameters | Positive mechanistic OECD CF level 2/3 Test | Scenario | Next step of the assessment  | Scenario selected |
|--|---|----------|--|-------------------|
| No (sufficiently investigated)             | Yes/No                                      | 1a       | Conclude: ED criteria not met because there is not "EAS-mediated" adversity  |                   |
| Yes (sufficiently investigated)            | Yes/No                                      | 1b       | Perform MoA analysis   |                   |
| No (not sufficiently investigated)         | Yes   | 2a (i)   | Perform MoA analysis (additional information may be needed for the analysis) |                   |

| Adversity based on EAS-mediated parameters | Positive mechanistic OECD CF level 2/3 Test | Scenario | Next step of the assessment  | Scenario selected |
|--|---|----------|--|-------------------|
| No (not sufficiently investigated)         | No (sufficiently investigated)              | 2a (ii)  | Conclude: ED criteria not met because no EAS-mediated endocrine activity observed  | x                 |
| No (not sufficiently investigated)         | No (not sufficiently investigated)          | 2a (iii) | Generate missing level 2 and 3 information. Alternatively, generate missing “EAS-mediated” parameters. Depending on the outcome move to corresponding scenario |                   |
| Yes (not sufficiently investigated)        | Yes/No                                      | 2b       | Perform MoA analysis   |                   |

#### 2.10.1.3.7. MoA analysis for EAS-modalities

According to the ED EFSA/ECHA guidance (2018), in cases of Scenario 2a (ii), a MoA analysis for EAS-modalities is not required.

#### 2.10.1.3.8. Conclusion on the assessment of EAS-modalities

Considering all the data available, there is no indication of endocrine activity and no adversity for the EAS modalities. Therefore, ED criteria are not met because no EAS-mediated effects have been observed and scenario 2a (ii) is selected.

#### 2.10.1.4. Overall conclusion on the ED assessment for humans

##### T-modality:

Considering the available data, T-mediated adversity has been found based on T-mediated parameters and T-mediated activity has not been sufficiently investigated. It corresponds to Scenario 1b. A MoA analysis is required and a conclusion cannot be reached.

##### EAS-modality:

Based on the available data, EAS-mediated adversity has been considered not sufficiently investigated, whereas EAS-mediated endocrine activity has been deemed sufficiently investigated.

E-modality: It is considered sufficiently investigated based on the estrogenic activity output data from the US EPA ToxCast Bioactivity Model.

A-modality: It is considered sufficiently investigated based on the output data from “Hershberger bioassay in rats” (ID: 31; OECD TG 441).

S-modality: It is considered sufficiently investigated based on the output data from “H295R Steroidogenesis assay” (ID: 30; OECD TG 456), and the “*In vitro* aromatase inhibition using human recombinant microsomes assay” (ID: 29) in line with OPPTS 890.1200.

No signs of adversity were found in the available dataset consistent in subacute, subchronic, chronic and reproductive toxicity studies conducted with dodine in different species. On the other hand, the positive anti-androgenic activity and the capacity of dodine to inhibit aromatase activity were not further confirmed in the follow up *in vitro* and *in vivo* studies, so the relevance of a potential dodine activity for the EAS modalities was ruled out. Therefore, the dodine does not meet the ED criteria for the EAS modalities and the scenario 2a (ii) applies.

#### 2.10.2 ED assessment for non-target organisms

Where the available evidence indicates that the ED criteria are not met for mammals as non-target organisms, the assessment for non-target organisms should proceed by considering fish and amphibians, because these are the taxa where standardised test methods and knowledge on how to interpret the results are available. Information on other organism (e.g. birds) should be considered if available.

For wild mammals, the main source of information are the regulatory toxicological studies performed with mammals in the laboratory for human safety purposes, which are summarized in Volume 3 (AS) Section B.6. The assessment for wild mammals should be based on the same data package. However, the determination of adverse effects will be different, as for wild mammals the focus is on effects that are relevant at the population level. It is noted that a separate assessment for wild mammals have not been submitted by applicant and can be requested once the conclusion on ED assessment for human health is reached. Regarding T- modality for mammals, T-mediated adversity was found based on T-mediated parameters and T-mediated activity was not sufficiently investigated. Then, a MoA analysis is required and a conclusion cannot be reached. Nonetheless, potential ED properties of Dodine on non-target organisms other than mammals was assessed for this modality.

In the case of the EAS modalities, the dataset for mammals showed that Dodine does not meet the criteria (see Point 2.3). Therefore, according to the strategy recommended in the ECHA/EFSA Guidance (2018), further consideration on the potential ED properties on non-target organisms other than mammals for these modalities is required.

The available studies in the RAR for Dodine were considered. A summary of all studies is provided below.

Data were populated in the Excel template provided as Appendix E to the EFSA/ECHA guidance for the identification of endocrine disruptors (2018). According to this template each study was given a unique identification number (Study ID Matrix) that is important for its identification in the data-matrix and Lines of Evidence (LoE) spreadsheets of the Excel.

**Table 2.10.3-1 Outline of dataset considered for ED assessment of non-target organisms**

| Type of toxicity                       | Study type  | Study ID Matrix |
|--|---|-----------------|
| <i>In vitro</i> mechanistic            | Refer to Table 2.10.1-1                                     | -               |
| Avian reproduction                     | Avian reproduction test in bobwhite quail (OECD 206)        | 56              |
|  | Avian reproduction test in bobwhite quail (OECD 206)        | 57              |
|  | Avian reproduction test in mallard duck (OECD 206)          | 58              |
| Long-term and chronic toxicity to fish | Fish early life stage toxicity in fathead minnow (OECD 210) | 59              |
| Endocrine disruption                   | Fish short-term reproduction assay (OECD 229)               | 60              |
|  | Amphibian metamorphosis assay (OECD 231)                    | 61              |

#### *Avian data*

The avian reproduction toxicity test (level 4 of the OECD CF), provide only apical endpoints that might be endocrine-sensitive but which cannot be considered specific for the identification of an endocrine MoA.

Three studies are available in the dossier investigating the effects of dodine on avian reproduction, two with bobwhite quail (one of them accepted as supporting information) and other with mallard duck.

**KCA 8.1.1.3./03; [REDACTED] 1999. Bobwhite quail (OECD 206):** The reproductive toxicity of Dodine to bobwhite quail (*Colinus virginianus*), fed ad libitum in the diet for a period of 21 weeks, was investigated. Effects of nominal test concentrations of 200, 600 and 1000 mg Dodine/kg diet, respectively, over 1 generation were compared to a control group. No treatment related effects were observed on body weight or food consumption of adults. Statistically significant differences in survival rate for offspring were noted on day 14 in the high dose group, therefore, a NOEC of 600 mg a.s./kg of feed was set. However, high mortality in the control (16%, 25% in females) identified a concern regarding the reliability of this study. Consequently this study was accepted as supporting information.

**KCA 8.1.1.3./03; [REDACTED] 1999. Bobwhite quail (OECD 206):** The reproductive toxicity of Dodine to bobwhite quail (*Colinus virginianus*), fed ad libitum in the diet for a period of 21 weeks, was investigated. Effects of nominal test concentrations of 75, 150 and 300 mg Dodine/kg diet, respectively, over 1 generation were compared to a control group. No signs of toxicity were observed at any of the concentrations tested. There were no apparent treatment-related effects in adults body weight, feed consumption and reproductive performance. Therefore, NOEC was 300 mg a.s./kg feed, the highest concentration tested (equivalent to 27 mg a.s./kg bw/d, based parental toxicity and reproduction).

**KCA 8.1.1.3./05; [REDACTED] 1994b. Mallard duck (OECD 206):** The reproductive toxicity of Dodine to mallard duck (*Anas platyrhynchos*), fed ad libitum in the diet for a period of 20 weeks, was investigated. Nominal test

concentration were : 0 (control), 200, 600 and 1000 mg a.s./kg diet. Statistically significant differences on body weight at 1000 mg a.s./kg feed and on food consumption at 600 and 1000 mg a.s./kg feed were observed in adults. Furthermore, significant differences on several reproductive effects and on the F1 generation in the mallard duck were reported (eggs laid per hen per day, %viable embryos, % live 21-day embryos of viable embryos, %14-day old survivors, dosy weight of 1-day old survivors, mean thickness). Therefore, a NOEC of 200 mg a.s./kg feed was set (equivalent to 17.0 mg a.s./kg body weight/day, based parental toxicity and reproduction).

### *Fish data*

A 34 d fish early life stage test (OECD TG 210, CF level 4) with fathead minnow (*Pimephales promelas*) and a 21-day Fish Short Term Reproduction Assay (OECD TG 229, CF level 3) with the same species were available.

**KCA 8.2.2.1/01, ██████████ 1995. Fish early life stage toxicity test with fathead minnow (*Pimephales promelas*) (OECD 210):** A 35-day early life-stage limit test under flow-through conditions was conducted on fathead minnow (*Pimephales promelas*). Embryos were exposed to 22, 44, 87, 170 and 350 µg Dodine/L, a solvent control containing methanol (0.01mL/L) and a dilution water control. At the end of hatching period (day 5), no effects on hatching of embryos were observed. Following 30-days post-hatch exposure (day 35), larval survival was reduced at the highest concentration (40% respect to a 91% reported in controls). Total length and weight of larval at 170 µg a.s./L was significantly reduced. No effects were observed at the remaining treatments. The lowest NOEC for chronic toxicity of Dodine technical to fathead minnow was 170 µg/L based on effects on larval survival, length and wet weight.

**KCA 8.2.3/01; ██████████ 2021. Fish Short Term Reproduction Assay with fathead minnow (*Pimephales promelas*) (OECD 229):** The study was performed under flow-through conditions to evaluate potential endocrine activity of dodine. Sexually mature and reproducing fish were exposed to nominal concentrations of 4.0, 20 and 100 µg/L (mean measured concentrations: 3.4, 18 and 85 µg/L). No significant differences on body weight, body length and fecundity were found. Secondary sexual characteristics in male fish did not indicate endocrine activity (no differences in number of tubercules per male fish were observed). A significant increase of plasma VTG levels compared to the pooled controls was found in males exposed to the highest concentration (85 µg/L), while in females, a decreased was reported. No correlation of the effects on VTG levels to other endpoints has been found. Histopathological results could not be assessed by RMS (images not available, **DATA GAP**). **Therefore, a conclusion on the ED properties of the test item could not be reached.** In addition, RMS has **concerns** about the results relevance, as the selected doses did not cover the MTC (as recommended in the ED guidance and OECD 229) and could be too low to elicit any possible ED mediated effect. The results of the study should be used in the risk assessment with caution, as it only showed the ED effects up to the highest concentration tested.

### *Amphibian data*

An amphibian metamorphosis assay (AMA) according to OECD TG 231 is available.

**KCA 8.2.3/02; ██████████ 2022. Amphibian metamorphosis assay (AMA) (OECD 231):** Lethal and sublethal effects as well as effects on the normal function of the hypothalamic-pituitary-thyroid (HPT) axis on tadpoles of *Xenopus laevis*, caused by the test item Dodine technical, were investigated. The tadpoles were exposed in a flow-through test during a period of 21 days to the nominal concentrations of 2.0, 10.0 and 50.0 µg/L (mean measured: 2.4, 5.8 and 29 µg/L), and to a control group consisting of aqueous test media and a solvent control group, containing the solvent dimethyl sulfoxide (DMSO). The study fulfilled the performance criteria reported in the OECD 231 guideline, except with the related to the variability of measured test concentrations over time, as CV was slightly above the limit. Considering the observed behavior of the test item in test medium, the outcome was considered acceptable. No significant differences on the development stage were observed. A reduction of wet weight (22%) and of the SVL (11%) were observed at the middle test concentration (5.8 µg/L) at day 7, and a slight increase of both parameters at the lowest concentration at the end of the assay were found (2.4 µg/L). These effects on wet weight and SVL were considered no dose-related. The normalized Hind Limb Length (by SVL) of larvae was significantly reduced at day 7 at the lowest concentration, and in all treatments at the end of the study for larvae at NF ≤ 60 (reduction 10-14%), but not for tadpoles above stage NF 60. However, as no acceleration of HLL development was found, the effects observed on this parameter were not considered thyroid-related. Normal morphological development of tadpoles was reported, then, no asynchronous development was identified. Histopathological results could not be assessed by RMS (images not available, **DATA GAP**). **Therefore, a conclusion on ED properties according the decision logic scheme reported in OECD 231 could not be reached.** In addition, RMS has **concerns** about the results relevance, as the selected doses did not cover the MTC (as recommended in the ED guidance and OECD 231) and could be too low to elicit any possible ED mediated effect. The results of the study should be used in the risk assessment with caution, as it only showed the ED effects up to the highest concentration tested.

**2.10.2.1 ED assessment for T-modality**

A summary of all studies considered for non-target organisms other than mammals, including the Study ID Matrix is outlined in Table 2.10.3.1-1.

**Table 2.10.3.1-1: Have T-mediated parameters been sufficiently investigated?**

|                                      | <b>Sufficiently investigated</b>   |
|--------------------------------------|--|
| <b>T-mediated adversity</b>          | <p>No, based on lack of the following study: LAGDA, OECD TG 241</p> <p>The following studies are available which include endpoints sensitive to, but not diagnostic of, EATS modalities:</p> <ul style="list-style-type: none"> <li>- Avian reproduction test, OECD TG 206, study IDs: 56 (KCA 8.1.1.3./02; ██████████ 1994a)</li> <li>- Avian reproduction test, OECD TG 206, study IDs: 57 (KCA 8.1.1.3./03; ██████████ 1999)</li> <li>- Avian reproduction test, OECD TG 206, study IDs: 58 (KCA 8.1.1.3./05; ██████████ 1994b)</li> <li>- Fish early life stage assay, OECD TG 210, study ID: 59 (KCA 8.2.2.1/01, ██████████ 1995)</li> <li>- Fish short term reproduction assay, OECD TG 229, study ID: 60 (KCA 8.2.3/01; ██████████ 2021)</li> <li>- Amphibian Metamorphosis Assay, OECD TG 231, study ID: 61 (KCA 8.2.3/02; ██████████ 2022)</li> </ul> |

2.10.2.1.1 Lines of evidence for adverse effects and endocrine activity related to T-modality

The tables below presented the lines of evidence based on applicant’s proposal updated by RMS to reflect RMS’s conclusion for each study.

| Study ID Matrix | Effect classification                     | Effect target                      | Species                                       | Duration of exposure | Duration unit | Route of administration | Lowest Effect dose | Dose unit | Effect direction | Observed effect (positive and negative)   | Assessment of each line of evidence   | Assessment on the integrated line of evidence  | Modality |
|-----------------|---|------------------------------------|---|----------------------|---------------|-------------------------|--------------------|-----------|------------------|---|---|--|----------|
| 61              | EATS-mediated                             | Developmental stage                | <i>Xenopus laevis</i>                         | 21                   | days          | Uptake from water       | > 29               | µg ai/L   | No effect        | No statistically significant differences were found in median sage (NF stage) at day 7 and day 21 up to the highest concentration tested.   | No effect   | The delayed development cannot be conclusively identified as generalized toxicity or antagonistic thyroid activity, since there were no significant effects on other indicators of developmental delays or relevant histopathological changes in the thyroid gland. <b>RMS:</b> a reliable conclusion could not be reached, as histopahtology could not be assessed by RMS (images not available, <b>DATA GAP</b> ). Additionally, RMS has <b>concerns</b> about representativeness of doses tested. | T        |
| 61              |   | Hind limb length                   | <i>Xenopus laevis</i>                         | 21                   | days          | Uptake from water       | 2.4                | µg ai/L   | Decrease         | A significant decrease of normalised HLL (by SVL) was observed at day 7 in larvae exposed to 2.4 µg ai/L and at day 21 in all treatments in larvae NF<60.   | Delayed development   |  |          |
| 61              |   | Thyroid histopathology (amphibian) | <i>Xenopus laevis</i>                         | 21                   | days          | Uptake from water       | > 29               | µg ai/L   | No effect        | No significant differences observed up to the highest concentration tested. Mild hypertrophy of follicular cells (grade 1) found in all groups, including controls. <b>RMS:</b> results were not assessed by RMS, images not available ( <b>DATA GAP</b> ). | Effect could not be discarded by RMS (images not available)   |  |          |
| 56              | Sensitive to, but not diagnostic of, EATS | Body weight (bird)                 | Bobwhite Quail ( <i>Colinus virginianus</i> ) | 24                   | Weeks         | Oral                    |                    | ppm       | No effect        | No significant differences on body weight of adults were found up to 1000 mg a.s./kg feed. <b>RMS:</b> Results should be considered with caution due to the high mortality observed in controls.  | A decrease of body weight of birds was reported in one of three studies performed. This decrease was observed in mallard duck, in adults at 1000 mg a.s./kg feed and in 1-day-old survivors from 600 mg a.s./kg. No effects in bobwhite quail were found. | <b>RMS:</b> Evidence of adverse effects on parameters sensitive to, but not diagnostic of, EATS-mediated parameters could not be discarded (effects on body weight of birds and fish, and length of fish reported)   | N        |

|    |                         |   |                         |       |                   |          |         |           |  |   |  |

**2.10.2.1.2 Assessment of the integrated lines of evidence and weight of evidence**

For non-target organisms other than mammals, no T-mediated activity and adversity were observed in the Amphibian Metamorphosis Assay up to the highest dose tested (OECD TG 231; study ID 61). Delayed development of larvae (decrease of HLL) was observed but it was not correlated to significant effects on developmental stage, asynchronous development or histopathological changes. The alterations in the thyroid glands found in tadpoles after 21-days of exposure were considered not test item-related. However, a reliable conclusion could not be reached, as histopathology could not be assessed by RMS (images not available, **DATA GAP**). Additionally, RMS has **concerns** about representativeness of doses tested. In the ecotoxicological studies with birds (OECD TG 206; study IDs: 56, 57 and 58) and with fish (OECD TG 210 and 229; study ID: 59 and 60), adverse effects on body weight and length were observed. Therefore, adverse effects on parameters rated as “sensitive to but not diagnostic of EATS” were found, although not assignable to a specific modality. No evidence of systemic toxicity in fish, birds and amphibians were found.

The studies which include information on the T-mediated endocrine activity and adversity are discussed in Table 2.10.3.1.2-1. For T-mediated adversity, only studies which included endpoints sensitive to, but not diagnostic of, EATS modalities are available.

**Table 2.10.3.1.2-1: Weight of evidence of T-mediated endocrine activity and adversity for non-mammalian vertebrates**

|   |
|---|
| <p><b>WoE for T-mediated activity:</b></p> <ul style="list-style-type: none"> <li>- <u>Amphibians</u>: in the Amphibian Metamorphosis Assay (OECD TG 231; study ID 61), no indications for advanced or asynchronous development or relevant histopathological changes induced by Dodine in the thyroid glands. The effects indicating delayed development (i.e. reduction of normalized HLL only in the NF &lt; 60 tadpoles) cannot be conclusively identified as generalized toxicity or antagonistic thyroid activity. It should be noted that HLL alone is ranked 3 for potential antagonist thyroid effects according to Borgert et al. (2014)<sup>13</sup>, due to systemic toxicity and non-hormonal activity. Dodine could be considered apparent thyroid inactive, although results should be considered with caution, histopathological images were not checked by RMS and there were concerns regarding the doses tested (it was performed below the MTC of the test item).</li> </ul>  |
| <p><b>WoE for T-related parameters “sensitive to but not diagnostic of EATS”:</b></p> <ul style="list-style-type: none"> <li>- <u>Birds</u>: in the Avian reproduction test (OECD TG 206; study IDs: 56, 57 and 58), only parameters not assignable to a specific modality were evaluated. Relevant effects on body weight of adults and 1-day old survivors were reported in mallard duck, but not in bobwhite quail. These effects on body weight were dose-related, therefore can be considered biologically relevant and adverse on a (sub)population level, but they cannot be assignable to a specific modality.</li> <li>- <u>Fish</u>: in the Fish early life stage assay (OECD TG 210; study ID: 59) adverse effects on body weight and length (decrease) were observed at 170 µg/L, but they cannot be assignable to a specific modality. Instead, in the Fish short-term reproduction assay (OECD 229; IDs: 60), no adverse effects on relevant parameters were found at the highest doses tested. However, it is noted that the last study was performed probably below the MTC of the test item.</li> <li>- <u>Amphibians</u>: in the Amphibian Metamorphosis Assay (OECD TG 231; study ID 61), no adverse effects or not dose-related on sensitive to, but not diagnostic of, EATS-mediated parameters were observed (body weight, Snout-vent length/growth). However, there were concerns regarding the doses tested (it was performed below the MTC of the test item) that could influence on reliability of result.</li> </ul> |
| <p><b>WoE for systemic toxicity:</b></p> <ul style="list-style-type: none"> <li>- <u>Birds</u>: in the Avian reproduction tests (OECD TG 206; study IDs: 56, 57 and 58), no evidences of systemic toxicity were reported. Effects on feed consumption of birds was observed in only in adults of mallard duck.</li> </ul>   |

<sup>13</sup> Borgert, C. J., Stuchal, L. D., Mihaich, E. M., Becker, R. A., Bentley, K. S., Brausch, J. M., Coady, K., Geter, D. R., Gordon, E., Guiney, P. D., Hess, F., Holmes, C. M., LeBaron, M. J., Levine, S., Marty, S., Mukhi, S., Neal, B. H., Ortego, L. S., Saltmiras, D. A., Snajdr, S., Staveley, J., Tobia, A. (2014): Relevance weighing of tier 1 endocrine screening endpoints by rank order. Birth Defects Research Part B. Developmental and Reproductive Toxicology; 101(1): 90 - 113

- Fish: in the Fish Early Life Stage Assay (OECD TG 210; study ID: 59) and in the Fish short-term reproduction assay (OECD 229; IDs: 60), no evidences of systemic toxicity were reported.
- Amphibians: in the Amphibian Metamorphosis Assay (OECD TG 231; study ID 61), no evidences of systemic toxicity were reported.

**2.10.2.1.3 Initial analysis of the evidence and identification of the relevant scenario**

No T-mediated adversity was observed. In order to consider T-mediated adversity with regard to non-target organisms sufficiently investigated, in principle a LAGDA (OECD TG 256) would be needed. This study was not performed; therefore, adversity is considered not sufficiently investigated. Moreover, adverse effects on sensitive to, but not diagnostic of, EATS-mediated parameters were reported in birds and fish, although not assignable to a specific modality. Regarding T-mediated activity, an amphibian metamorphosis assay was performed, in which the T-mediated parameters were apparently negative (development delay observed but not correlated with other apical indicators). According to the ECHA/EFSA guidance, a negative result in T-mediated parameters in the AMA is sufficient to support that T-mediated adversity is unlikely because no T-related endocrine activity has been observed. However, (i) histopathological results were not checked by RMS (DATA GAP), then a reliable conclusion could not be reached; and (ii) RMS highlighted concerns regarding if the highest tested concentration in AMA was enough to elicit any possible ED mediated effect, as they were not close to the MTC (no mortality observed). Consequently, there are uncertainties to reach a conclusion on the ED properties of the substance with the AMA performed, T-mediated activity was not considered sufficiently investigated.

Overall, this leads to the selection of scenario 2a(iii) “generate missing level 2 and 3 information. Alternatively, generate missing “EATS-mediated” parameters. Depending on the outcome move to corresponding scenario” (see Table 2.10.3.1.3-1).

In order to avoid unnecessary animal testing, outcome of ED assessment in humans should be considered before generate more information.

**Table 2.10.3.1.3-1 Selection of relevant scenario**

| Adversity based on T-mediated parameters | Positive mechanistic OECD CF level 2/3 Test | Scenario | Next step of the assessment   | Scenario selected |
|--|---|----------|---|-------------------|
| No (sufficiently investigated)           | Yes/No                                      | 1a       | Conclude: ED criteria not met because there is not “T-mediated” adversity   | -                 |
| Yes (sufficiently investigated)          | Yes/No                                      | 1b       | Perform MoA analysis  | -                 |
| No (not sufficiently investigated)       | Yes   | 2a (i)   | Perform MoA analysis (additional information may be needed for the analysis)  | -                 |
| No (not sufficiently investigated)       | No (sufficiently investigated)              | 2a (ii)  | Conclude: ED criteria not met because no T-mediated endocrine activity observed   | -                 |
| No (not sufficiently investigated)       | No (not sufficiently investigated)          | 2a (iii) | Generate missing level 2 and 3 information. Alternatively, generate missing “EATS-mediated” parameters. Depending on the outcome move to corresponding scenario | X                 |
| Yes (not sufficiently investigated)      | Yes/No                                      | 2b       | Perform MoA analysis  | -                 |

**2.10.2.1.4 MoA analysis for T-modality**

Not relevant.

**2.10.2.1.5 Conclusion on the ED assessment for T-modality**

The outcome of the assessment reported above for humans also applies to wild mammals as non-target organisms. A MoA analysis is required, as T-mediated adversity was found based on T-mediated parameters and T-mediated activity was not sufficiently investigated.

For non-target organisms other than mammals, the endocrine disruption potential of dodine through the T-modality could not be drawn since the endocrine activity/endocrine adversity was not sufficiently investigated. There are uncertainties to reach a conclusion on the ED properties of the substance. Further information should be generated, scenario 2a(iii). In order to avoid unnecessary animal testing, outcome of ED assessment in humans should be considered before generate more information.

**2.10.2.2 ED assessment for EAS-modality**

A summary of all studies considered for non-target organisms other than mammals, including the Study ID Matrix is outlined in Table 2.10.3.2-1.

**Table 2.10.3.2-1 Have EAS-mediated parameters been sufficiently investigated?**

|                                 | <b>Sufficiently investigated?</b>   |
|---------------------------------|---|
| EAS-mediated adversity          | <p>No, based on lack of the following studies:<br/>MEOGRT (OECD TG 240) or FLCTT (OPPTS 850.1500).</p> <p>The following studies are considered in ED assessment which include endpoints sensitive to, but not diagnostic of, EATS modalities:</p> <ul style="list-style-type: none"> <li>- Avian reproduction test, OECD TG 206, study IDs: 56 (KCA 8.1.1.3./02; ██████████ 1994a)</li> <li>- Avian reproduction test, OECD TG 206, study IDs: 57 (KCA 8.1.1.3./03; ██████████ 1999)</li> <li>- Avian reproduction test, OECD TG 206, study IDs: 58 (KCA 8.1.1.3./05; ██████████ 1994b)</li> <li>- Fish early life stage assay, OECD TG 210, study ID: 59 (KCA 8.2.2.1/01, ██████████ 1995)</li> <li>- Fish short term reproduction assay, OECD TG 229, study ID: 60 (KCA 8.2.3/01; ██████████ 2021)</li> <li>- Amphibian Metamorphosis Assay, OECD TG 231, study ID: 61 (KCA 8.2.3/02; ██████████ 2022)</li> </ul> |

| 57 | Feed consumption (adult)     | Bobwhite Quail ( <i>Colinus virginianus</i> ) | 21 | Weeks | Oral | -   | ppm | No effect | No significant differences were found up to the highest dose tested         |  |
| 58 | Feed consumption (offspring) | Mallard Duck ( <i>Anas platyrhynchos</i> )    | 20 | Weeks | Oral | -   | ppm | No effect | No significant differences were found up to the highest dose tested         |  |
| 58 | Feed consumption (adult)     | Mallard Duck ( <i>Anas platyrhynchos</i> )    | 20 | Weeks | Oral | 600 | ppm | Decrease  | A decrease of food consumption was observed at 600 and 1000 mg a.s./kg feed |  |

### 2.10.2.2.2 Assessment of the integrated lines of evidence and weight of evidence

Based on the statistically significant effects of Dodine on the plasma vitellogenin levels in female and male fish at the highest mean measured test concentration of 85 µg/L observed in the fish short-term reproduction assay (OECD TG 229; study ID 60), it cannot be excluded that Dodine technical affects the normal function of the HPG axis in fathead minnow. Taking into account that neither tubercle number and tubercle score, nor fecundity and histopathology indicate any endocrine effect, the effect on the plasma VTG levels is most likely a false positive result. This is supported by the reported high variability of the VTG concentration in males and females, rendering VTG levels alone without any relation to effects on other endpoints indicative of endocrine disruption an unreliable indicator. However, a reliable conclusion could not be reached, as histopathology could not be assessed by RMS (images not available, **DATA GAP**), and RMS has **concerns** about representativeness of doses tested. In the ecotoxicological studies with birds (OECD TG 206; study IDs: 56, 57 and 58) and with fish (OECD TG 210 and 229; study ID: 59 and 60), several adverse effects on parameters rated as “sensitive to but not diagnostic of EATS” were found, although not assignable to a specific modality. No evidence of systemic toxicity in fish, birds and amphibians were found.

The studies which include information on the EAS-mediated endocrine activity and adversity are discussed in Table 2.10.3.2.2-1.

**Table 2.10.3.2.2-1: Weight of evidence of EAS-mediated endocrine activity and adversity for non-mammalian vertebrates**

|   |
|---|
| <p><b>WoE for EAS-mediated activity:</b></p> <ul style="list-style-type: none"> <li>- <u>Fish</u>: significant effects on vitellogenin content (VTG) in males and females were observed in the Fish Short-Term Reproduction Assay (OECD TG 229; study ID 60). However, there was no indication of EAS related activity, since no correlation of effects on VTG to other endpoints found (secondary sexual characteristics, histopathological assessment of gonads, fecundity), although results should be considered with caution, histopathological images were not checked by RMS and there were concerns regarding the doses tested (it was performed below the MTC of the test item).</li> </ul>  |
| <p><b>WoE for EAS-mediated adversity:</b></p> <ul style="list-style-type: none"> <li>- <u>Fish</u>: in the Fish Short-Term Reproduction Assay (OECD TG 229; study ID 60), no relevant effects were observed in the gonadal histopathology, nor were any of secondary sexual characteristics affected. Results should be considered with caution, histopathological images were not checked by RMS and there were concerns regarding the doses tested (it was performed below the MTC of the test item).</li> </ul>  |
| <p><b>WoE for EAS-related parameters “sensitive to but not diagnostic of EATS”:</b></p> <ul style="list-style-type: none"> <li>- <u>Birds</u>: in the Avian reproduction test (OECD TG 206; study IDs: 56, 57 and 58), only parameters not assignable to a specific modality were evaluated. A decrease of body weight of adults and 1-day old survivors, egg production, egg viability, embryos viability and eggshell thickness were reported in mallard duck, but not in bobwhite quail. Effects on survival of 14 day-old birds was also found in both species. All these adverse effects were dose-related, therefore can be considered biologically relevant and adverse on a (sub)population level, but they cannot assignable to a specific modality.</li> <li>- <u>Fish</u>: in the Fish Early Life Stage Assay (OECD TG 210; study ID: 59), adverse effects (decrease) on body weight, survival of embryos, larval survival and length were observed at 170 µg/L. All these effects were dose-related, and they can be considered biologically relevant and adverse on a (sub)population level, but they cannot assignable to a specific modality. Instead, in the Fish short-term reproduction assay (OECD 229; IDs: 60), no adverse effects on relevant parameters were found up to 85 µg/L (e.g. body weight, length, fecundity, fertility, length, malformations). However, it is noted that the FSTRA was performed below the MTC of the test item (RMS has <b>concerns</b> about representativeness of doses tested).</li> <li>- <u>Amphibians</u>: in the Amphibian Metamorphosis Assay (OECD TG 231; study ID 61), no adverse effects or not dose-related on sensitive to, but not diagnostic of, EATS-mediated parameters were observed (body weight, Snout-vent length/growth). However, there were <b>concerns</b> regarding the doses tested (it was performed below the MTC of the test item) that could influence on reliability of results.</li> </ul> |
| <p><b>WoE for systemic toxicity:</b></p> <ul style="list-style-type: none"> <li>- <u>Birds</u>: in the Avian reproduction tests (OECD TG 206; study IDs: 56, 57 and 58), no evidences of systemic toxicity were reported. Effects on feed consumption of birds was observed in only in adults of mallard duck.</li> </ul>   |

- Fish: in the Fish Early Life Stage Assay (OECD TG 210; study ID: 59) and in the Fish short-term reproduction assay (OECD 229; IDs: 60), no evidences of systemic toxicity were reported.
- Amphibians: in the Amphibian Metamorphosis Assay (OECD TG 231; study ID 61), no evidences of systemic toxicity were reported.

**2.10.2.2.3 Initial analysis of the evidence and identification of the relevant scenario**

In order to consider EAS-mediated adversity with regard to non-target organisms sufficiently investigated, a Medaka extended one-generation test (MEOGRT; OECD TG 240) or Fish life cycle toxicity test (FLCTT; OPPTS 850.1500) would be needed. These studies were not performed, therefore, adversity is considered not sufficiently investigated. The endocrine activity for the EAS-modalities could be considered sufficiently investigated since Fish Short-Term Reproduction Assay (OECD TG 229) was performed, and in which not test substance-related effects on EAS-mediated activity were observed (effects on VTG content but not correlated with other apical endpoints). However, (i) histopathological results were not checked by RMS (DATA GAP), and (ii) RMS highlighted concerns regarding if the highest tested concentration in FSTRA was enough to elicit any possible ED mediated effect, as they were not close to the MTC (no mortality observed). Consequently, there are uncertainties to reach a conclusion on the ED properties of the substance with this test, and EAS-mediated activity was not considered sufficiently investigated. Moreover, several adverse effects on “sensitive to, but not diagnostic of, EATS-mediated parameters” were reported in birds and fish that can be considered biologically relevant and adverse on a (sub)population level, although not assignable to a specific modality.

Overall, this leads to the selection of scenario 2a(iii) “generate missing level 2 and 3 information. Alternatively, generate missing “EATS-mediated” parameters. Depending on the outcome move to corresponding scenario (see Table 2.10.3.1.3-1). In order to avoid unnecessary animal testing, outcome of ED assessment in humans should be considered before generate more information.

**Table 2.10.3.1.3-1 Selection of the relevant scenario**

| Adversity based on EAS-mediated parameters | Positive mechanistic OECD CF level 2/3 Test | Scenario | Next step of the assessment   | Scenario selected |
|--|---|----------|---|-------------------|
| No (sufficiently investigated)             | Yes/No                                      | 1a       | Conclude: ED criteria not met because there is no “EAS-mediated” effect   | -                 |
| Yes (sufficiently investigated)            | Yes/No                                      | 1b       | Perform MoA analysis  | -                 |
| No (not sufficiently investigated)         | Yes   | 2a (i)   | Perform MoA analysis (additional information may be needed for the analysis)  | -                 |
| No (not sufficiently investigated)         | No (sufficiently investigated)              | 2a (ii)  | Conclude: ED criteria not met because no EAS mediated effect observed   | -                 |
| No (not sufficiently investigated)         | No (not sufficiently investigated)          | 2a (iii) | Generate missing level 2 and 3 information. Alternatively, generate missing “EATS-mediated” parameters. Depending on the outcome move to corresponding scenario | X                 |
| Yes (not sufficiently investigated)        | Yes/No                                      | 2b       | Perform MoA analysis  | -                 |

**2.10.2.2.4 MoA analysis for EAS-modalities**

Not relevant.

#### 2.10.2.2.5 Conclusion on the ED assessment for EAS-modality

The outcome of the assessment reported above for humans also applies to wild mammals as non-target organisms.

For non-target organisms other than mammals, the endocrine disruption potential of dodine through the EAS-modalities could not be drawn since the endocrine activity/endocrine adversity was not sufficiently investigated. There are uncertainties to reach a conclusion on the ED properties of the substance. Further information should be generated scenario 2a(iii).

### 2.11 PROPOSED HARMONISED CLASSIFICATION AND LABELLING ACCORDING TO THE CLP CRITERIA [SECTIONS 1-6 OF THE CLH REPORT]

#### 2.11.1 Identity of the substance [section 1 of the CLH report]

### 2.11.3 History of the previous classification and labelling

Dodine is a fungicide used as an active substance in plant protection products (PPP). It was included in Annex I to Directive 91/414/EEC (Commission Directive 2011/9/EC) and it has been deemed to be approved under Commission Implementing Regulation (EU) No 540/2011 in accordance with Regulation (EC) No 1107/2009. With Commission Implementing Regulation (EU) No 2020/2007, the expiry date of the approval of Dodine was set to 31.08.2024.

Regarding the renewal of dodine as an active substance in the context of PPP Regulation, a Renewal Assessment Report (RAR) in accordance with Commission Regulation (EC) No. 2020/1740 is being developed by the Spanish CA.

At the time of submission of this CLH report, dodine is currently listed in Annex VI of Regulation (EC) 1272/2008 and it is classified as Aquatic Acute 1, Aquatic Chronic 1 without setting M factors. The actual classification derives from Directive 67/548/EEC. In this CLH report, harmonized classification is maintained and M factors are proposed as M = 100 and M = 1 for acute and chronic hazard, respectively.

### 2.11.4 Identified uses

Dodine is an active substance used for plant protection products. It is used as a fungicide on pome fruits and stone fruits.

The representative uses evaluated comprise foliar spraying against scab in apples and pears, and against leaf curl and leaf spot diseases in peaches and cherries, respectively.

### 2.11.5 Data sources

This CLH Report is based on the available information provided within the dossier submitted for the renewal process (AIR IV) of dodine as active substance as plant protection product under regulation (EC) 1107/2009. Data are exposed and evaluated in the respective volume 3 of the dRAR (2023) performed by Spain.

## 2.12 RELEVANCE OF METABOLITES IN GROUNDWATER

No major metabolites were identified for the active substance. Hence, information under this point is not required. Consequently, an assessment of the relevance of the metabolites according to the principles set out in the relevant guidance document, SANCO/221/2000, is not required.

### 2.12.1 STEP 1: Exclusion of degradation products of no concern

No major metabolites were identified for the active substance. Hence, information under this point is not required. Consequently, an assessment of the relevance of the metabolites according to the principles set out in the relevant guidance document, SANCO/221/2000, is not required.

### 2.12.2 STEP 2: Quantification of potential groundwater contamination

No major metabolites were identified for the active substance. Hence, information under this point is not required. Consequently, an assessment of the relevance of the metabolites according to the principles set out in the relevant guidance document, SANCO/221/2000, is not required.

### 2.12.3 STEP 3: Hazard assessment – identification of relevant metabolites

### **2.12.3.1 STEP 3, Stage 1: screening for biological activity**

### **2.12.3.2 STEP 3, Stage 2: screening for genotoxicity**

### **2.12.3.3 STEP 3, Stage 3: screening for toxicity**

No major metabolites were identified for the active substance. Hence, information under this point is not required. Consequently, an assessment of the relevance of the metabolites according to the principles set out in the relevant guidance document, SANCO/221/2000, is not required.

### **2.12.4 STEP 4: Exposure assessment – threshold of concern approach**

No major metabolites were identified for the active substance. Hence, information under this point is not required. Consequently, an assessment of the relevance of the metabolites according to the principles set out in the relevant guidance document, SANCO/221/2000, is not required.

### **2.12.5 STEP 5: Refined risk assessment**

No major metabolites were identified for the active substance. Hence, information under this point is not required. Consequently, an assessment of the relevance of the metabolites according to the principles set out in the relevant guidance document, SANCO/221/2000, is not required.

### **2.12.6 Overall conclusion**

No major metabolites were identified for the active substance. Hence, information under this point is not required. Consequently, an assessment of the relevance of the metabolites according to the principles set out in the relevant guidance document, SANCO/221/2000, is not required.

## **2.13 CONSIDERATION OF ISOMERIC COMPOSITION IN THE RISK ASSESSMENT**

### **2.13.1 Identity and physical chemical properties**

Since the active substance is not an isomeric compound, the isomeric composition has not to be taken into consideration.

### **2.13.2 Methods of analysis**

Since the active substance is not an isomeric compound, the isomeric composition has not to be taken into consideration.

### **2.13.3 Mammalian toxicity**

Since the active substance is not an isomeric compound, the isomeric composition has not to be taken into consideration.

### **2.13.4 Operator, Worker, Bystander and Resident exposure**

Since the active substance is not an isomeric compound, the isomeric composition has not to be taken into consideration.

### **2.13.5 Residues and Consumer risk assessment**

Since the active substance is not an isomeric compound, the isomeric composition has not to be taken into consideration.

### **2.13.6 Environmental fate**

Since the active substance is not an isomeric compound, the isomeric composition has not to be taken into consideration.

### 2.13.7 Ecotoxicology

Since the active substance is not an isomeric compound, the isomeric composition has not to be taken into consideration.

## 2.14 RESIDUE DEFINITIONS

### 2.14.1 Definition of residues for exposure/risk assessment

**Food of plant origin: (fruits) RD-RA 1: Dodine**  
**RD-RA 2: Guanidine (tentative)**

**Food of animal origin:** Dodine. Definition set to parent compound by default.

**Soil:** Dodine

**Groundwater:** Dodine

**Surface water:** Dodine

**Sediment:** Dodine

**Air:** Dodine

### 2.14.2 Definition of residues for monitoring

**Food of plant origin:** Dodine

**Food of animal origin:** Dodine. Definition set to parent compound by default.

**Soil:** Dodine

**Groundwater:** Dodine

**Surface water:** Dodine

**Sediment:** Dodine

**Air:** Dodine

# Level 3

# DODINE

**3 PROPOSED DECISION WITH RESPECT TO THE APPLICATION**

**3.1 BACKGROUND TO THE PROPOSED DECISION**

**3.1.1 Proposal on acceptability against the decision making criteria – Article 4 and annex II of regulation (EC) No 1107/2009**

| <b>3.1.1.1 Article 4</b> |  | Yes | No |  |
|--------------------------|--|-----|----|--|
| i)                       | It is considered that Article 4 of Regulation (EC) No 1107/2009 is complied with. Specifically the RMS considers that authorisation in at least one Member State is expected to be possible for at least one plant protection product containing the active substance for at least one of the representative uses. | X   |    | <p>Dodine is a foliar fungicide with protective and some curative action. According to its mode of action, dodine is a multisite inhibitor acting mainly on the fungus membranes with not systemic but translaminar action. It penetrates partially in the leaves and stops the disease.</p> <p>The representative formulation Dodine 544 SC is intended to be used up to 2 times per season to apples/pear, cherry and peach with minimum application intervals of 21 days. The maximum application rates (per application) range between 0.68 kg a.s./ha (apples/pear and cherry) to 0.9 kg a.s./ha (peach), equivalent to 1.25 L product/ha and 1.65 L product/ha, respectively.</p> <p><i>Fate and behaviour in the environment:</i></p> <ul style="list-style-type: none"> <li>• <b>Groundwater:</b></li> <li>- 80th percentile annual average concentration in leachate at 1 m depth (PEC<sub>gw</sub>) for dodine are below the trigger value of 0.1 µg/L in all relevant scenarios. Therefore, it is concluded that an unacceptable risk to groundwater after application of Dodine 544 according to the GAP is not expected.</li> </ul> <p><i>Ecotoxicology:</i></p> <ul style="list-style-type: none"> <li>• <b>Birds and mammals:</b></li> <li>- Exposure of birds to dodine according to the GAP shows no unacceptable risks in <b>apples/pear and cherry in the Central Zone</b> based on the outcome of the higher tier risk assessment. However, all refinements (except interception value) were representative for the Central Zone, their extrapolation to other regulatory zones needs further justification/applicability may need further consideration at Member State level.</li> </ul> |

|  |  |  |   |
|--|--|--|---|
|  |  |  | <ul style="list-style-type: none"> <li>- <i>Exposure of mammals to dodine according to the GAP shows no unacceptable risks, with the exception of:</i> <ul style="list-style-type: none"> <li>o <i>apple/pear at BBCH&lt;10 (unacceptable risk for vole identified)</i></li> <li>o <i>cherry at postharvest (unacceptable risk for vole and dormouse identified)</i></li> <li>o <i>peach (unacceptable risk for vole identified).</i></li> </ul> </li> </ul> <p><i>Refinements were representative for the Central Zone, their extrapolation to other regulatory zones requires further justification and their applicability may need further consideration at Member State level.</i></p> <ul style="list-style-type: none"> <li>• <b>Aquatic organisms:</b></li> </ul> <ul style="list-style-type: none"> <li>- <i>Exposure of aquatic organisms to dodine according to the GAP shows no unacceptable risks for the intended uses if the following mitigation measures are implemented.</i> <ul style="list-style-type: none"> <li>o <i>When ETO-RAC is considered: 20 m no-spray buffer zone + 90% drift reducing nozzles for late applications on apple/pear, cherry and peach, and summer applications on cherry. |--|--|--|--|---|

**3.1.1.2 Submission of further information**

|     |   | Yes | No |
|-----|---|-----|----|
| i)  | It is considered that a complete dossier has been submitted   | X   |    |
| ii) | It is considered that in the absence of a full dossier the active substance may be approved even though certain information is still to be submitted because: |     |    |

|   |                  |           |   |
|---|------------------|-----------|---|
| <p>(a) the data requirements have been amended or refined after the submission of the dossier; or<br/>                 (b) the information is considered to be confirmatory in nature, as required to increase confidence in the decision.</p>  |                  |           |   |
| <p><b>3.1.1.3 Restrictions on approval</b></p>  |                  |           |   |
| <p>It is considered that in line with Article 6 of Regulation (EC) No 1107/2009 approval should be subject to conditions and restrictions.</p>  | <p>Yes<br/>X</p> | <p>No</p> |   |
| <p><b>3.1.1.4 Criteria for the approval of an active substance</b></p>  |                  |           |   |
| <p><b>Dossier</b></p>   |                  |           |   |
| <p>It is considered the dossier contains the information needed to establish, where relevant, Acceptable Daily Intake (ADI), Acceptable Operator Exposure Level (AOEL) and Acute Reference Dose (ARfD).</p>   | <p>Yes<br/>X</p> | <p>No</p> |   |
| <p>It is considered that the dossier contains the information necessary to carry out a risk assessment and for enforcement purposes (relevant for substances for which one or more representative uses includes use on feed or food crops or leads indirectly to residues in food or feed). In particular it is considered that the dossier:</p> <p>(a) permits any residue of concern to be defined;</p> <p>(b) reliably predicts the residues in food and feed, including succeeding crops</p> <p>(c) reliably predicts, where relevant, the corresponding residue level reflecting the effects of processing and/or mixing;</p> <p>(d) permits a maximum residue level to be defined and to be determined by appropriate methods in general use for the commodity and, where appropriate, for products of animal origin where the commodity or parts of it is fed to animals;</p> <p>(e) permits, where relevant, concentration or dilution factors due to processing and/or mixing to be defined.</p> | <p>X</p>         |           | <p>Three plant metabolism studies investigating the metabolic pathway of dodine on fruits crops (apples, strawberries, pecans) are available and considered valid in compliance to OECD guideline 501. However, qualitative differences are observed between apples/strawberry and pecans. In order to cover the representative uses with long PHIs, the RMS deems advisable to submit a new study in another fruit crop.</p> <p>For the evaluation of the metabolism in livestock, a goat metabolism study is available and considered acceptable. It is expected that the levels of the metabolites identified in edible tissues would be very low at the dietary intake calculated.</p> <p>A complete residue data package is available to support the representative uses of Dodine in pome fruits and peach, in southern and northern zone. However not enough trials are available for cherries according to the intended GAP in both zones (data gap).</p> <p>One hydrolysis study was submitted and considered acceptable and three apple processing studies were performed. The number of trials is considered sufficient to derive robust processing factors for apple juice, wet pomace and canned apples. Processing factor for apple juice may be extrapolated to other pome (pear) or stone fruits (peach).</p> |

|                                 |   |     |    |   |
|---------------------------------|---|-----|----|---|
|                                 |   |     |    | <p>One study for determination of residues of dodine in phacelia honey under semi-field conditions was submitted and considered acceptable.</p> <p>Representative uses (apple, cherry, peach) are perennial crops, therefore, data on the metabolism or magnitude of residues in rotational crops are not required</p>  |
|                                 | It is considered that the dossier submitted is sufficient to permit, where relevant, an estimate of the fate and distribution of the active substance in the environment, and its impact on non-target species.   |     |    |   |
| <b>Efficacy</b>                 |   |     |    |   |
|                                 |   | Yes | No |   |
|                                 | It is considered that it has been established for one or more representative uses that the plant protection product, consequent on application consistent with good plant protection practice and having regard to realistic conditions of use is sufficiently effective. | X   |    | <p>Dodine is intended to be used as a fungicide against scab (<i>Venturia inaequalis/Venturia pyrina</i>) on pome fruits (Apple/Pear), leaf spot (<i>Blumeriella jaapii</i>) on cherry and leaf curl (<i>Taphrina deformans</i>) on peach, nectarine. Dodine is fungitoxic in action preventing disease infection and establishment. Dodine has a translaminar action and penetrates partially in the leaves and stops the disease. It is a multisite inhibitor acting mainly on the fungus membranes. Dodine is currently used as a fungicide on pome fruits (apple/pear/quince/medlar/loquat), on cherry, peach and nectarine, olives, walnut, chestnut and pistachios, almonds, and poplar. Representative uses for this application are pome fruit, cherry, and peach. FRAC evaluates the general risk for development of resistance against Dodine as low to medium. The crop safety of the representative uses has already been evaluated under Uniform Principles for national registration and found acceptable. Therefore, no specific data on phytotoxicity is required. The representative uses have already been evaluated under Uniform Principles for national registration and found acceptable. Therefore, no information regarding observations on other undesirable or unintended side effects is required.</p> |
| <b>Relevance of metabolites</b> |   |     |    |   |
|                                 |   | Yes | No |   |
|                                 | It is considered that the documentation submitted is sufficient to permit the establishment of the toxicological, ecotoxicological or environmental relevance of metabolites.   | X   |    | <p>Based on the results of soil degradation studies, no metabolites were found in soil at proportions &gt; 10% AR, 5% AR in two consecutive samples and/or &gt;5% at the end of the study. Thus dodine is the only compound to be further considered in groundwater risk assessment.</p>  |
| <b>Composition</b>              |   |     |    |   |
|                                 |   | Yes | No |   |
|                                 | It is considered that the specification defines the minimum degree of purity, the identity and maximum content of impurities and, where relevant, of isomers/diastereo-isomers and additives, and the content of  | X   |    | <p><i>The minimum purity of the active substance Dodine proposed by the applicant is 980 g/kg</i><br/> <i>Purity for the first approval (Commission Directive 2011/9/EU): 950 g/Kg</i></p>  |

|                               |   |     |    |   |
|-------------------------------|---|-----|----|---|
|                               | impurities of toxicological, ecotoxicological or environmental concern within acceptable limits.  |     |    | <i>It does not contain impurities of toxicological, ecotoxicological and/or environmental concern.</i>  |
|                               | It is considered that the specification is in compliance with the relevant Food and Agriculture Organisation specification, where such specification exists.  | X   |    | <i>FAO specification (101/TC/S (1988) (AGP:CP/236)): Dodine: min. 950 g/kg</i>  |
|                               | It is considered for reasons of protection of human or animal health or the environment, stricter specifications than that provided for by the FAO specification should be adopted  |     |    | <i>Not applicable</i>   |
| <b>Methods of analysis</b>    |   |     |    |   |
|                               |   | Yes | No |   |
|                               | It is considered that the methods of analysis of the active substance, safener or synergist as manufactured and of determination of impurities of toxicological, ecotoxicological or environmental concern or which are present in quantities greater than 1 g/kg in the active substance, safener or synergist as manufactured, have been validated and shown to be sufficiently specific, correctly calibrated, accurate and precise. |     | X  | <i>For active substance: HPLC-UV (specificity not demonstrated). Please see Level 2, point 2.5.1.1<br/>There are not relevant impurities<br/>For significant impurities: LC-MS/MS and GC-MS/MS. Please see Vol 4 of DRAR (confidential)</i>   |
|                               | It is considered that the methods of residue analysis for the active substance and relevant metabolites in plant, animal and environmental matrices and drinking water, as appropriate, shall have been validated and shown to be sufficiently sensitive with respect to the levels of concern.   |     | X  | <b>Crops:</b> <i>High Water content plants (GC-MSD with LOQ of 0.05 mg/kg), Acidic Crop Matrices (LC/MS/MS with LOQ of 0.01 mg/kg), High Oil content plants (LC/MS/MS with LOQ of 0.01 mg/kg) and Dry Crop Matrices (LC/MS/MS with LOQ of 0.01 mg/kg).</i><br><b>Animal origin:</b> <i>LC/MS/MS with LOQ of 0.01 mg/kg. ILV required for honey</i><br><b>Soil:</b> <i>GC/MS with LOQ of 0.01 mg/kg and LC/MS/MS with LOQ of 0.01 mg/kg</i><br><b>Surface Water:</b> <i>LC/MS/MS with LOQ of 0.008 µg/L and LC/MS/MS with LOQ of 0.05 µg/L</i><br><b>Drinking Water:</b> <i>LC/MS/MS with LOQ of 0.008 µg/L and LC/MS/MS with LOQ of 0.05 µg/L. ILV required for drinking water</i><br><b>Air:</b> <i>LC/MS/MS with LOQ 0.00850 mg/absorber (0.1xC-level) Validation required at LOQ ≤ 0.00173 mg dodine/absorber</i><br><b>Body fluids and tissues:</b> <i>in tissues (liver) dodine is determined by LC/MS/MS with LOQ of 0.01 mg/kg and the metabolite hydroxy-dodecylguanidine with LOQ of 5.0 µg/kg (a confirmatory method is required for the metabolite) ; in body fluids (human blood and urine) dodine and the metabolite hydroxy-dodecylguanidine are determined by LC/MS/MS with LOQ of 2 µg/L (a confirmatory method is required for dodine and the metabolite).</i> |
|                               | It is confirmed that the evaluation has been carried out in accordance with the uniform principles for evaluation and authorisation of plant protection products referred to in Article 29(6) of Regulation 1107/2009.  | X   |    |   |
| <b>Impact on human health</b> |   |     |    |   |

| Impact on human health - ADI, AOEL, ARfD                               |     |    |  |
|--|-----|----|--|
|  | Yes | No |  |
|  | X   |    | Toxicological reference values can be established. After the assessment, the following values are proposed:<br>ADI = 0.02 mg/kg bw/day<br>AOEL = 0.008 mg/kg bw/day<br>ARfD = 0.1 mg/kg bw   |
| Impact on human health – proposed genotoxicity classification          |     |    |  |
|  | Yes | No |  |
|  |     | X  | Dodine has been tested for potential genotoxic properties (gene mutation, clastogenicity and aneugenicity) in a group of in vitro and in vivo assays. In any of them dodine showed evidence of genotoxic potential. Therefore, the evaluation of available information leads to the conclusion that dodine should not be classified as mutagenic.  |
| Impact on human health – proposed carcinogenicity classification       |     |    |  |
|  | Yes | No |  |
| i)   |     | X  | Two long-term chronic and carcinogenicity studies were presented with dodine, one in rats and one in mice.<br>In the chronic toxicity/carcinogenicity study in rats, an increase in the incidence of combined thyroid adenomas and carcinomas was observed.<br>In the chronic toxicity/carcinogenicity study in mice, increased incidences of hepatocellular adenomas were observed, but they were not considered as treatment-related adverse effects.<br>The RMS proposes the classification of dodine as Carc. 2 (H351).          |
| ii)  |     |    | Linked to above classification proposal.<br>It is considered that exposure of humans to the active substance, safener or synergist in a plant protection product, under realistic proposed conditions of use, is negligible, that is, the product is used in closed systems or in other conditions excluding contact with humans and where residues of the active substance, safener or synergist concerned on food and feed do not exceed the default value set in accordance with Article 18(1)(b) of Regulation (EC) No 396/2005. |
| Impact on human health – proposed reproductive toxicity classification |     |    |  |
|  | Yes | No |  |
| i)   |     | X  | Neither adverse effects on sexual function and fertility, nor developmental effects in the absence of maternal toxicity, nor effects on or via lactation, have   |

|   |  |     |    |   |
|---|--|-----|----|---|
|   | the active substances, safeners or synergists and other available data and information, including a review of the scientific literature, reviewed by the Authority, <b>the substance SHOULD BE classified or proposed for classification</b> , in accordance with the provisions of Regulation (EC) No 1272/2008, <b>as toxic for reproduction category 1A or 1B</b> .   |     |    | been identified. Therefore, no classification of dodine is expected as toxic for reproduction.  |
| ii)   | Linked to above classification proposal.<br>It is considered that exposure of humans to the active substance, safener or synergist in a plant protection product, under realistic proposed conditions of use, is negligible, that is, the product is used in closed systems or in other conditions excluding contact with humans and where residues of the active substance, safener or synergist concerned on food and feed do not exceed the default value set in accordance with Article 18(1)(b) of Regulation (EC) No 396/2005. |     |    |   |
| <b>Impact on human health – proposed endocrine disrupting properties classification</b> |  |     |    |   |
|   |  | Yes | No |   |
| i)  | It is considered that <b>the substance SHOULD BE identified as having endocrine disrupting properties</b> in accordance with the provisions of point 3.6.5 in Annex II of Regulation (EC) No 1107/2009   |     |    | Considering the available data, T-mediated adversity has been found. It corresponds to Scenario 1b: a MoA analysis is required.<br><br>Based on the available data, EAS-mediated adversity has been considered not sufficiently investigated, whereas EAS-mediated endocrine activity has been deemed sufficiently investigated. Therefore, the scenario 2a(ii) applies: the dodine does not meet the ED criteria for the EAS modalities. |
| ii)   | Linked to above identification proposal.<br>It is considered that exposure of humans to the active substance, safener or synergist in a plant protection product, under realistic proposed conditions of use, is negligible, that is, the product is used in closed systems or in other conditions excluding contact with humans and where residues of the active substance, safener or synergist concerned on food and feed do not exceed the default value set in accordance with Article 18(1)(b) of Regulation (EC) No 396/2005. |     |    |   |
| <b>Fate and behaviour in the environment</b>  |  |     |    |   |
| <b>Persistent organic pollutant (POP)</b>   |  |     |    |   |
|   |  | Yes | No |   |
|   | It is considered that the active substance <b>FULFILS</b> the criteria of a persistent organic pollutant (POP) as laid out in Regulation 1107/2009 Annex II Section 3.7.1.   |     | X  | <b>1.- Persistence criterion</b><br><br><b>Soil system:</b> The aerobic degradation of Dodine was determined in 5 different soils at 20/25°C. Dodine degraded rapidly in soil with persistence DT50 values  |

|  |  |  |  |
|--|--|--|--|
|  |  |  | <p>at 20°C ranging from 2.9 to 17 days (not corrected for moisture). DT90 values ranged from 9.7 to 35.7 days. The persistence criterion was not fulfilled in any soil. A data gap has been identified for a new study investigating anaerobic degradation in soil.. Moreover, photolysis does not play a significant role for Dodine degradation in soil. Please, refer to Level 2 pont 2.8.1.2 for further details</p> <p><b>Based on all available data, it is concluded that the P-criteria in soil is not fulfilled for dodine.</b></p> <p><b>Aquatic system:</b> Dodine is hydrolytically stable in water under without significative pH dependence. It was found to be not readily biodegradable under the conditions of the modified Sturm test.</p> <p>DT50 values for [14C]guanidine-labelled Dodine in natural surface water were calculated to be 2.3 days.</p> <p>Dodine dissipated rapidly (DT50water &lt; 1 day) from the water phase by mineralisation (up to 89 % AR after 84 days), and partitioning to the sediment (up to 27.5 % AR after 1 hour). In the sediment dodine dissipates rapidly, decreasing to &lt; 5 % AR after 5 days. Unextracted sediment residues increased to 58 % AR and 35 % AR after 1 day, and decreased to 33 % AR and 14 % AR in the total system at study end. DT50 in the whole water sediment systems &lt; 1d</p> <p><b>Based on all available data, it is concluded that the P-criteria in water is not fulfilled for dodine.</b></p> <p><b><u>2.- Bioaccumulation criterion</u></b></p> <p>Although Dodine is stable in water (less than 90% loss of the original substance over 24 h via hydrolysis), it has a log Pow &lt; 3 and therefore no test investigating its bioconcentration potential in fish was required. <b>Dodine does not meet the criterion of bioaccumulation.</b></p> <p><b><u>3.- Toxicity criterion</u></b></p> <p><b>Dodine is very toxic to aquatic organisms.</b> The effects on invertebrates and algae drive the aquatic risk assessment.</p> |
|--|--|--|--|

|   |  |     |    |  |
|---|--|-----|----|--|
|   |  |     |    | <p><b>4.- Atmospheric Long-range transport</b></p> <p>The DT50 in air is estimated using the Atkinson calculation. The total OH rate constant was determined at <math>1.0876 \times 10^{-10} \text{ cm}^3 \text{ molec. sec}</math>. Half-life in the troposphere was calculated to be 1.180 hours for overall OH rate constant. Therefore, long-range transport is not relevant (trigger is DT50 &gt;2 days).</p>   |
| <b>Persistent, bioaccumulative and toxic substance (PBT)</b>      |  |     |    |  |
|   |  | Yes | No |  |
|   | It is considered that the active substance <b>FULFILS</b> the criteria of a persistent, bioaccumulative and toxic (PBT) substance as laid out in Regulation 1107/2009 Annex II Section 3.7.2.  |     | X  | Please refer to paragraph above  |
| <b>Very persistent and very bioaccumulative substance (vPvB).</b> |  |     |    |  |
|   |  | Yes | No |  |
|   | It is considered that the active substance <b>FULFILS</b> the criteria of a very persistent and very bioaccumulative substance (vPvB) as laid out in Regulation 1107/2009 Annex II Section 3.7.3.  |     | X  | Please refer to paragraph above  |
| <b>Ecotoxicology</b>  |  |     |    |  |
|   |  | Yes | No |  |
| i   | It is considered that the risk assessment demonstrates risks to be acceptable in accordance with the criteria laid down in the uniform principles for evaluation and authorisation of plant protection products referred to in Article 29(6) under realistic proposed conditions of use of a plant protection product containing the active substance, safener or synergist. The RMS is content that the assessment takes into account the severity of effects, the uncertainty of the data, and the number of organism groups which the active substance, safener or synergist is expected to affect adversely by the intended use. | X   |    | <p><i>Please, refer to Level 2.9 for further details</i></p> <ul style="list-style-type: none"> <li>• <b>Birds and mammals:</b></li> <li>• <i>Exposure of birds to dodine according to the GAP shows no unacceptable risks in <b>apples/pear and cherry in the Central Zone</b> based on the outcome of the higher tier risk assessment. However, all refinements (except interception value) were representative for the Central Zone, their extrapolation to other regulatory zones needs further justification/applicability may need further consideration at Member State level.</i></li> <li>• <i>Exposure of mammals to dodine according to the GAP shows no unacceptable risks, with the exception of:</i> <ul style="list-style-type: none"> <li>○ <i>apple/pear at BBCH&lt;10 (unacceptable risk for vole identified)</i></li> <li>○ <i>cherry at postharvest (unacceptable risk for vole and dormouse identified)</i></li> <li>○ <i>peach (unacceptable risk for vole identified).</i></li> </ul> </li> </ul> |

|  |  |  |   |
|--|--|--|---|
|  |  |  | <p><i>Refinements were representative for the Central Zone, their extrapolation to other regulatory zones requires further justification and their applicability may need further consideration at Member State level.</i></p> <ul style="list-style-type: none"> <li>• <b>Aquatic organisms:</b></li> <li>• <i>Exposure of aquatic organisms to dodine according to the GAP shows no unacceptable risks for the intended uses if the following mitigation measures are implemented.</i> <ul style="list-style-type: none"> <li>○ <i>When ETO-RAC is considered: 20 m no-spray buffer zone + 90% drift reducing nozzles for late applications on apple/pear, cherry and peach, and summer applications on cherry. Unacceptable risk was identified for early applications on apple/pear and peach.</i></li> <li>○ <i>When ERO-RAC is considered:</i> <ul style="list-style-type: none"> <li>▪ <i>50 m no-spray buffer zone for early applications on apple/pear and peach.</i></li> <li>▪ <i>25 m no-spray buffer zone for late applications on apple/pear, cherry and peach and summer applications on cherry.</i></li> </ul> </li> </ul> </li> </ul> <p><i>Supporting evidence of efficacy of the mitigation measures requiring a drift reduction above 95% should be provided. The ERO-RAC is representative for the Central Zone, the suitability of its use in the risk assessment (extrapolation to other regulatory zones) and the applicability of each particular mitigation measure should be assessed at the Member State level.</i></p> <p><i>For the postharvest use on cherry and peach, unacceptable risk for aquatic organisms was identified.</i></p> <ul style="list-style-type: none"> <li>• <b>Bees:</b></li> <li>- <i>Exposure of bees to dodine according to the GAP shows no unacceptable risks on honey bee brood or honey bee colony survival for all the intended uses based on the results of two semi-field studies carried out in the central and in the southern zone. Since some effects on mortality were observed in one trial for the exposure period, the following mitigation measure is proposed:</i></li> </ul> |

|---|--|--|--|--|

**3.1.5 Issues that could not be finalised**

An issue is listed as an issue that could not be finalised where there is not enough information available to perform an assessment, even at the lowest tier level, for the representative uses in line with the Uniform Principles, as laid out in Commission Regulation (EU) No 546/2011, and where the issue is of such importance that it could, when finalised, become a concern (which would also be listed as a critical area of concern if it is of relevance to all representative uses).

| Area of the risk assessment that could not be finalised on the basis of the available data   | Relevance in relation to representative use(s) |
|--|--|
| 1. ED assessment on T-modality   | All uses                                       |
| 2. ED assessment for non-target organisms:<br><br>Regarding T- modality for mammals, T-mediated adversity was found based on T-mediated parameters and T-mediated activity was not sufficiently investigated, then, a MoA analysis is required.<br><br>Considering the available information of non-target organisms other than mammals, RMS has concluded that neither adversity nor EAST-mediated endocrine activity has been sufficiently investigated. Further information should be generated (scenario 2a(iii)) to reach a conclusion on the ED properties of the substance. | All uses                                       |
|  |  |
|  |  |
|  |  |

**3.1.6 Critical areas of concern**

An issue is listed as a critical area of concern:

- (a) where the substance does not satisfy the criteria set out in points 3.6.3, 3.6.4, 3.6.5 or 3.8.2 of Annex II of Regulation (EC) No 1107/2009 and the applicant has not provided detailed evidence that the active substance is necessary to control a serious danger to plant health which cannot be contained by other available means including non-chemical methods, taking into account risk mitigation measures to ensure that exposure of humans and the environment is minimised, or
- (b) where there is enough information available to perform an assessment for the representative uses in line with the Uniform Principles, as laid out in Commission Regulation (EU) 546/2011, and where this assessment does not permit to conclude that for at least one of the representative uses it may be expected that a plant protection product containing the active substance will not have any harmful effect on human or animal health or on groundwater or any unacceptable influence on the environment.

An issue is also listed as a critical area of concern where the assessment at a higher tier level could not be finalised due to a lack of information, and where the assessment performed at the lower tier level does not permit to conclude that for at least one of the representative uses it may be expected that a plant protection product containing the active substance will not have any harmful effect on human or animal health or on groundwater or any unacceptable

influence on the environment.

| Critical area of concern identified | Relevance in relation to representative use(s)   |
|-------------------------------------|--|
|                                     | <i>[specify if concern relates to all or specific representative use/use scenario/product or to all uses/products]</i> |
|                                     |  |
|                                     |  |
|                                     |  |
|                                     |  |

**3.1.7 Overview table of the concerns identified for each representative use considered**

(If a particular condition proposed to be taken into account to manage an identified risk, as listed in 3.3.1, has been evaluated as being effective, then ‘risk identified’ is not indicated in this table.)

All columns are grey as the material tested in the toxicological studies has not been demonstrated to be representative of the technical specification.

| Representative use   |  | Apple/Pear     | Cherry         | Peach          |
|--|--|----------------|----------------|----------------|
| Operator risk  | Risk identified                                    |                |                |                |

The superscript numbers in this table relate to the numbered points indicated within chapter 3.1.5 and 3.1.6. Where there is no superscript number, see level 2 for more explanation.

(a): Value for non relevant metabolites prescribed in SANCO/221/2000-rev 10-final, European Commission, 2003

### 3.1.8 Area(s) where expert consultation is considered necessary

It is recommended to organise a consultation of experts on the following parts of the assessment report:

| Area(s) where expert consultation is considered necessary       | Justification  |
|---|--|
| Refined risk assessment of non-target soil macro- and mesofauna | The Tier 1 risk assessment indicated a high risk for <i>Folsomia candida</i> after early applications of dodine on peach. To refine the risk assessment, one toxicity test with <i>Folsomia candida</i> conducted in a natural soil was available. Currently there is no guidance on what natural soil properties would be |

|  |   |
|--|---|
|  | acceptable. RMS considers that this is a general issue that should be discussed with MMSS and EFSA. |
|  |   |
|  |   |
|  |   |
|  |   |

**3.1.9 Critical issues on which the Co RMS did not agree with the assessment by the RMS**

Points on which the co-rapporteur Member State did not agree with the assessment by the rapporteur member state. Only the points relevant for the decision making process should be listed.

| <b>Issue on which Co-RMS disagrees with RMS</b> | <b>Opinion of Co-RMS</b> | <b>Opinion of RMS</b> |
|---|--------------------------|-----------------------|
|   |                          |                       |
|   |                          |                       |
|   |                          |                       |
|   |                          |                       |
|   |                          |                       |

**3.2 PROPOSED DECISION**

It is proposed that:

**DODINE can be approved or renewed under Regulation (EC) No 1107/2009**

It is considered that the following be specified in Part B of the Commission Implementing Regulation as areas requiring particular attention from Member States when evaluating applications for product authorisation(s):

- *the potential long-term risk to birds and mammals;*
- *the risk to aquatic organisms and ensure that conditions of use impose adequate*
- *risk mitigation measures;*

It is considered that it should be specified that conditions of use shall include risk mitigation measures, where appropriate.

It is proposed that the Member States concerned shall request the submission of confirmatory information:

- (a) where new data requirements are established during the evaluation process, or
- (b) as a result of new scientific and technical knowledge, or
- (c) to increase confidence in the decision.

**3.3 RATIONAL FOR THE CONDITIONS AND RESTRICTIONS TO BE ASSOCIATED WITH THE APPROVAL OR AUTHORISATION(S), AS APPROPRIATE**

**3.3.1 Particular conditions proposed to be taken into account to manage the risks identified**

| Proposed condition/risk mitigation measure | Relevance in relation to representative use(s)  |
|--|---|
|  | <i>[specify if measure relates to a specific representative use/use scenario/product or to all uses/products]</i> |
|  |   |
|  |   |
|  |   |
|  |   |
